Most of our inexperienced readers will defer forcing for a month or two. In the beginning of the week we shall fill a shelf in a pit with plants that showed flower trusses prematurely in the open air, and which we set in a cool house where they have had no frost. Soon we shall fill a frame with Black Prince and Keens' Seedling, giving them just a little heat to start them gently. There will be a gentle heat from leaves, &c., and we shall set the pots on the surface, or each on a tile, board, or slate. The Strawberry dislikes much bottom heat, and, therefore, beginners would do well never to plunge a pot in a bed when starting it. It will be almost sure to set the leaves growing very freely, whilst the flower truss will be left behind. However started, the forcing in winter, and especially early in spring, must be very gradual, commencing with from 40° to 45°, and mounting up very gradually in a month to 50° and 55°, and then slowly to 60°. Thus Strawberry plants placed in such a house as a Peach house before it is started succeed remarkably well, as the changes are so gradual, and better than in a pit for early forcing, as there is more room for air and sunshine. A high temperature at once for early Strawberries is the best of all modes of insuring failure.

Though the plants should not be dry, the soil should be somewhat dry rather than wet, until the truss shows freely. They should have no water in a pan until the fruit is set and swelling, and but little then. It is better to water oftener. In watering before the truss shows, avoid watering overhead. In dull weather this is apt to damp off the bud.

Many who see how hardy their Strawberry plants are growing in the open garden, may consider all this care with pots to fruit early quite unnecessary, but they should recollect that the plant in a pot is placed in artificial circumstances, and must be treated accordingly. A hardy plant that no rains or frosts would injure when growing in the natural soil, may be very easily killed, or much injured when growing in a pot standing freely exposed on the surface of the ground, or waterlogged when plunged. When pots strong though porous, are often in such cases cracked and split, how will the tender roots escape? Last winter some enthusiastic amateurs had their Strawberry pots, and fine plants, too, standing exposed on the side of a walk after New Year's-day. We did not wonder that the fine plants gave anything but satisfaction at fruiting time.

ORNAMENTAL DEPARTMENT.

Raking, sweeping, and rolling, have been the routine work, and we placed rough half-rotten manure on lines of Gladiolus, as we could not just now find a place to our mind to store the bulbs. We have had a pit emptied of the rotten manure, and supplied with fresh, preparatory to the gentle forcing of shrubs and a few tender plants. Now is a good time for setting apart the most rotten of such manure to come in as leaf mould, when well aired and sweetened. The charred rubbish lately referred to is also valuable for this purpose, it sweetens and lightens every soil.

Many of our bedding and other plants were in rather dark and damp places, and clearing out some places has enabled us to move them into other frames, where they would receive all the light in this dull season, the frames being raised higher at the back the better to catch the rays of light. Some of the plants had a few warm leaves placed beneath, and then dry ashes to set them on. We thus filled a frame with pots of Mignonette beginning to show bloom, and if there be any signs of damping the pots will be moved to drier heat. Roses and Deutzias will be placed in a gentle heat.

We are glad we put some *Violets* under glass, as the late frost has hurt and taken the scent from the Russian Violet in the open air. Could we manage to spare a two-light box we would next week put a foot or so of hot dung beneath it, 3 inches of rotten dung, and then cram it with Russian Violets taken up with balls, and packed with rich loam, and then come frost or not we should be sure of sweet-scented Violets. Would some experienced grower tell us of the properties of the new sorts advertised—the reds, pinks, &c ?

We potted off some annuals for early blooming, as Collinsias. Gave more room to Cinerarias and Primulas, and took forward plants of both to the conservatory. The climbers there we have had greatly to reduce to admit light for the winter. A little shade in summer is all very well. On the pruning of climbers we shall have something to say. When established, according to the treatment given, they will do well spurred-in like a Currant, or flowered on the young wood like a Raspberry.

In all houses where merely a temperate heat is maintained ranging from 38° to 45° at night, great care should be taken not to spill water about, as that is apt to rise by evaporation, be condensed against the glass, and then in cold weather when much air cannot be given, fall like a shower bath over the plants, and most likely in the very places where it is not wanted.

Heating must be attended to with great care in this very changeable weather. It is always safest rather to underdo than overdo, and is sure to be more economical too. The fall of the temperature in a house for a few degrees is safer and better for the plants than roasting them with a high dry heat. It is much more pleasant to put an extra shovelful on the fire than to pull a great fire out of a furnace. We lately discussed fully the whole subject of furnace management. It is too often a matter of haphazard and waste. Three simple things are essential to be attended to by him who would manage the heating of plant houses well. First, he must learn to read the signs of the weather in the sky, at least for short periods, and then he will be less likely to overheat his houses at night, and still more unlikely to allow a strong sun heat and a strong artificial heat to meet together during the day, and more especially if under these circumstances there should be a dry, biting frosty air. Secondly, he must examine the outside thermometer before going into his houses, and thence make his comparisons. Thirdly, he will not only look at the thermometer in the house, if not so practised as to know within a degree or two when he enters, but he will likewise feel his pipes or flues, &c., and all this he will do before going to the furnace. We put the question in all earnestness, Is it so common to find these simple precautions attended to? Is it, indeed, so common for youths even to condescend to place their hand on a pipe or a flue? Is it not quite as common to see a man the first thing in a morning bustle into a stokehole and set a fire going, without previously troubling himself about any one of these matters? We shall say nothing now of keeping furnaces clear, regulating dampers, keeping furnaces and ashpit doors shut, and thus, in the case of boilers, doing something to keep the heat about the boiler, instead of sending more than half of it up the chimney into the general atmosphere.—R. F.

TRADE CATALOGUES RECEIVED.

Kelway & Son, Langport, Somerset.—*Catalogue of Gladioli.*

William Chater, Saffron Walden.—*Catalogue of Hollyhocks and Roses.*

COVENT GARDEN MARKET.—November 17.

Prices remain nearly stationary, although our market stands are much better cleared than they were. Apples and Pears continue in good request. Pine Apples and Grapes are sufficient for the demand. Foreign imports are light. The Potato trade is more active.

TO CORRESPONDENTS.

*** We request that no one will write privately to any of the correspondents of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely to The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

Books (*A Monthly Reader*).—Rivers's "Rose Amateur's Guide," free by post for 4*s.*; "Fruit-Gardening for the Many," 4*d.*; "Poultry Book," 6*d.* You can have it and the latter two from our office, if you send with your address the amount in stamps, with two stamps additional. There are no articles such as you refer to.

Vines in Orchard House (*A. Q.*).—We are glad to hear that you have been so successful in your cultivation of Grapes without the aid of fire heat. It serves to show so well what can be done by taking good care of that which we have—sun heat. Your list already includes the leading varieties suitable for your purpose, but as you seem fond of variety, we would recommend White Frontignan, a highly flavoured sort. Foster's White Seedling is a very good sort, but not so highly flavoured as the other. Ingram's Prolific is not at all times a satisfactory grower; therefore, we should not recommend it, excepting as an experiment. Royal Ascot is a most excellent sort, free-bearing, and of fine flavour, and we should think, although we have not proved it, suitable for your cool orchard-house. Try it.

Edible Fungus (*F. A., East Retford*).—Your fungus is Agaricus personatus, a well-known edible species, distinguished from its allies by the pale purple tint round the top of the stem.

Chenopodium (*L. W.*).—Being a native of Brazil, it would require greenhouse culture, and would, therefore, be too expensive to cultivate as chicken food. As you do not know the species, we cannot state the treatment the plant would require.

British Wild Flowers (*B. J. C.*).—The work will be continued until all our native flowering plants are portraited. The plates and descriptions may be bound in their numerical order, because classified indices are intended to be published when the work is completed.

Heating by Gas (*F. G., Anerley*).—You can readily exclude frost from your small greenhouse by means of gas. If you enclose four postage stamps with your address, and order No. 341 of this Journal, you will there see drawings and descriptions of various modes of gas-heating, and from them select that which you prefer. (*R. H.*).—A gas-heated stove will answer for heating a greenhouse if there is a chimney to take away the fumes. A saucer filled with water should be kept on the top of the stove. The cause of the Pelargonium leaves becoming yellow and drooping, is their being recently put into boxes.

Dwarf Peas (*Idem*).—The ground ought now to be trenched or deeply dug, and a good dressing of manure given, though it may be well in case the manure is rotten, not to apply it until February or March, and then fork it well into the ground, mixing it with the soil. For early sowing, Tom Thumb, and Little Gem (Maclean), both for February or March sowing, when Bishop's Long-podded may be sown at fortnightly or more distant intervals up to July. They are dwarf sorts and will do without sticks.

Transplanting a Cedar of Lebanon (*A. G. F. C.*).—It may be safely removed now in mild weather, care being taken to secure a good ball. If, however, the weather be frosty, planting ought to be deferred until March. The plant should be planted so that the uppermost roots will not be covered with more than 3 inches of soil, and if the ground is wet it would be well to plant on the surface, or on a mound. Secure the tree against wind, and give water in dry weather. Rich loam, light rather than heavy, is the most suitable soil. No manure is required. The top spit of a pasture taken off with the turf, and chopped up small, will answer perfectly well.

Various (*Patelin*).—The Cockchafer grub is the "Ver blanc" of the French, and we fear it would not avail if we told them they applied a wrong name. Fallen fruit will not keep under any circumstances, the extra damage to it from a brick edging must be very trifling, and the trouble of keeping Box in order, and the harbour it affords for vermin, are far more serious.

Evergreens for Stable Yard Walls (*Co. Antrim*).—There are no evergreen climbers except Ivy, which would suit the position you name. We have not noticed Ivy injure walls, and that is what we advise, especially as you say Escallonia macrantha and Berberis Darwinii are often injured by frost. You do not name the aspect, but we conclude that it is not south or west, as the Escallonia and Berberis succeed there in much colder localities. Cotoneaster buxifolia is a good handsome evergreen, but C. Simmondsii is more ornamental on account of its fruit. C. microphylla is also close-growing and evergreen. All three would suit you, and so would Crataegus pyracantha and Ligustrum japonicum.

Price of Bulbs and Seeds (*Clericus*).—There are none sold at such prices as you name. The usual prices seem high, but when the limited demand, loss from stock unsold, &c., are considered, the prices are not very excessive. There is so much opposition, that lower prices would be charged if they would enable a seedsman to live.

Croton pictum Treatment (*Eve*).—It requires a stove, a light moderately airy position, and plenty of room. In shade it becomes badly coloured. At this season give no more water than enough to keep the leaves fresh, and in March repot the plant, employing a compost of two parts fibrous loam, and one part peat, with a fourth part of leaf soil and old cow dung, adding sand liberally. Give good drainage, and remove as much of the old soil as can be done without injury to the roots. Water the plants carefully until the roots are working well in the fresh soil, then water it freely, and by maintaining a moist atmosphere, and brisk heat of from 65° to 70° at night, and 75° by day, with a rise on fine days to 85° or 90°, the plant will grow well. Have the foliage dry by the time the sun shines powerfully on the house. A gentle syringing in the evening will do good. A winter temperature of 60° at night, and 65° by day, with a rise of from 10° to 15° from sun heat should be maintained. Keep the soil moist, but not wet in winter.

Camellia Flower-buds Falling (*Anxiety*).—In the majority of cases the buds fall from a defective root action, the roots become inert by being grown in a close, imperfectly drained soil. The roots are kept more healthy in an open free soil than in one which becomes in a short time a close mass. The top of a pasture where the soil is a sandy loam, taken off an inch thick, pulled to pieces by the hand, is the best soil we know. Pot firmly. Sudden changes of temperature and irregularity in watering will also cause the buds to fall; too much water destroys the roots, and too little deprives the foliage of the needful support, and though the buds may not immediately fall, they do so when they ought to be swelling. Another cause is maintaining such an amount of heat and moisture as to cause a second growth, and the plants cast many, if not all their buds. After the buds are set the plants cannot be kept too cool and well aired. They are ruined by being kept in too much heat, and in an imperfectly ventilated atmosphere. Camellias are all but hardy, not needing half the amount of heat to which they are often subjected. Camellias are successfully propagated in this country.

Pine Apple Leaves Spotted (*A. G.*).—The leaf sent is spotted owing to moisture having dripped on it, and the evil may date from the time you name, for the spot is very small at first, and when it begins spreads rapidly. The spot is also a result of cold arising from the roots being in a wet soil, and inactive. It may also be a consequence of recent potting. Preserve a drier atmosphere, and keep the plants near the glass, with plenty of room sideways. We should think the plants weak if the leaf sent is a specimen.

Various (*A Lady Subscriber*).—The shoot sent we should say was of the Damson, but it is difficult to distinguish between a young shoot of Sloe and Damson. Mrs. Pince's Muscat Grape Vine requires more heat than the Golden Champion, the latter succeeding in the same temperature as Black Hamburghs, and being equally good for forcing or cool vineries. Mrs. Pince is a late Grape, and like all Muscats requires a high heat. Both are good Grapes. February would be sufficiently early to start seedling Vines for fruiting, though you may place them in a vinery in December; the house not be forced until January or February. Cliveden Pansy, and Viola cornuta, ought, for spring blooming, to have been divided at the end of September or beginning of October, but this may now be done in mild weather, the divisions being large and well-rooted.

Evergreen Trees for Shelter (*W. J.*).—The situation being exposed none of those you name would succeed. Nothing would serve you so well as the Austrian Pine. Of those you mention, the Berberry, Arbor-Vitæ, and Juniper would answer best, but we doubt their being sufficiently hardy. We should have Austrian Pines at back, with Hollies in front.

Agave americana variegata Treatment (*An Old Subscriber*).—We should consider the fault to be in the soil, it being too rich. Turfy loam, sandy rather than heavy, with a fourth part each of charcoal or crocks about the size of hazel nuts, and old cow dung, will grow it well, good drainage being provided. Little or no water will be required in winter, and in summer it will suffice if a good supply be given when the soil becomes dry. We should attribute the dying of the leaves to the points being injured, though it may be occasioned by moisture dripping on them. Place the plants out of doors in June, and house them before frost. Do not pot too often, but allow the pot to fill with roots.

Passion-Flower for a Greenhouse (*Idem*).—Passiflora cærulea racemosa and Comte Nesselrode are both good. Tacsonia Van-Volxemi is the most ornamental of Passion-Flower-like plants for a greenhouse.

Herbaceous Plants (*O. F. W. R.*).—Though we give you a list of plants that will flower between August and June, we do not say they will succeed in a border where there are many trees and shrubs, and the soil in winter very wet and cold. It is a question what will grow in such a position:—Adonis vernalis, Ajuga alpina, Alyssum saxatile, Anemone apennina, A. japonica, Arabis albida, Aubrietia grandiflora, Bellis perennis aucubæfolia, Cerastium tomentosum, Cheiranthus alpinus, C. Marshalli, Convallaria majalis and its varieties; Cyclamen neapolitanum, C. repandum, C. coum, C. europæum; Crocus sativus, C. nudiflorus; Dielytra spectabilis, Dodecatheon meadia, Draba aizoides, Eranthis hyemalis, Galanthus plicatus, G. nivalis and var. plenus; Gentiana acaulis, G. verna; Helleborus niger, Hepatica angulosa, H. triloba, vars. pink, blue, and white; Iberis Tenoreana, Iris reticulata, Leucojum vernum, Lythrum roseum superbum, Muscari botryoides, Myosotis montana, Narcissus Ajax, N. juncifolius, Orobus vernus, Paeonia in variety, Phlox verna, Primula acaulis, vars. double lilac, dark crimson, sulphur, and white, P. Auricula; Pulmonaria angustifolia, Scilla sibirica, Silene Schafta, Sternbergia lutea, Trollius europæus and its variety albus, T. asiaticus, T. napellifolius; Zephyranthes candida.

Roses for a Town Garden (*Idem*).—None do so well as the Hybrid perpetuals, and we have found those named succeed tolerably well:—

Alexandrine Bachmeteff, Anna Alexieff, Beauty of Waltham, Caroline de Sansal, Comte de Nanteuil, Comtesse de Chabrillant, Dr. Rushpler, Duchess of Norfolk, Duchess of Sutherland, Eugène Appert, François Premier, General Washington, Jacques Lafitte, Jean Bart, Jules Margottin, Le Lion des Combats, Lord Raglan, Louise Odier, Madame Boll, Madame Eugénie Verdier, Madame Julie Daran, Madame Frudeaux, Madame Vidot, Maréchal Vaillant, Marie Dauvesse, Marquis of Ailsa, Monsieur de Montigny, Pius IX., Senateur Vaisse, Triomphe d'Amiens, Victor Verdier, William Jesse, Reine des Violettes, and Princesse Mathilde.

Roses for a West Wall (*Wm. M. M.*).—You will not have room for more than three plants, though if your wall is a high one, you may plant them 3 instead of 6 feet apart. Having no sun until 2 P.M., Acidalie and Sir Joseph Paxton, both Bourbon, would suit, and Gloire de Dijon for the best position.

Dung for a Hotbed (*Idem*).—Horse droppings from a stable where sawdust is used would make good hotbeds, but heat violently, and ought to be mixed with litter or leaves in equal proportions. The heat is then more durable and less violent.

Gathering Late Pears (*Anxious*).—Late Pears, however hard and firm, should be gathered before they are frosted. If in pots under glass, they may remain longer on the trees. When we have allowed late Pears to have from 4° to 7° of frost, although they did not appear to suffer, we always thought they kept the worse, and were deficient in flavour.

Variegated Mangold Wurtzel (*Dublin*).—From your description and what we see of the dried leaf of Mangold, the plant must have been very striking. Nothing can be asserted as to the seed from the plant producing others equally variegated without trying it. The root will be quite safe anywhere in a dormant state all the winter, provided it is not frosted or eaten by vermin. Plant out in spring, and when the shoots approach flowering, cover with gauze, so as to let plenty of light and air in, and keep insects, &c., out.

Protecting Fruit Trees (*R. H. A.*).—Your plan will do. We presume you mean to have a wall-plate on the top of your 5-feet upright pieces. We would in the length of 100 feet have eight, the uprights stronger—viz., 4 by 3 inches. The front glass would do of 16-oz., as hail seldom breaks the front. We presume you will have ventilation at the top. Your house, with the exception of not being so high in front, will resemble the cold houses at Trentham. If we wanted to make the most of such a space of glass, we would have the house wider, and lower in front.

Heating a Vinery (*C., Subscriber*).—The best mode of heating your house would be by hot water. A cheaper mode would be by a small flue all the length of the house, or if you intended forcing much, having two furnaces in the centre, and a flue right and left. The flue would cost least at first, and much less for firing. Hot water, however, would be the best. For such a house you would require two, three, or four 4-inch pipes according to the heat wanted.

Pit Painted Inside with Gas Tar (*A. M. A.*).—So long as the smell remains it will not be possible to keep any growing plants in the pit. There is no remedy but scraping off every bit of the tar, and that would be easier done if you covered it with a thick wash of lime. This repeated once or twice may enable you to take the most of it off. If you do not do something of this kind, the pit will be of no use until the tar has become thoroughly hardened by the sun of a following summer. Not long ago a number of houses had to be emptied because the hot-water pipes were painted with tar, and beautifully the pipes looked. We advised a gentle heat in the pipes, oiling them well to soften the tar, and scraping it off—a very tedious business. Will any of our readers supply our correspondent and ourselves with a simple mode of neutralising or preventing the fumes from tar?

Cocoa-nut Fibre Refuse in Stoves (*L.*).—We do not think that cocoa-nut refuse is so apt to harbour woodlice, worms, &c., as tan or decaying leaves. It is a very cleanly material in which to plunge plants in a pit, and it retains heat well when given, but it is a bad conductor, especially when at all dry, and not good for making heat, or letting heat pass. Thus, suppose there were some source of bottom heat, and you had 1 foot or 18 inches of cocoa-nut fibre over it, and the pots set on it and partly plunged in it, they would have little bottom heat; but if the pots were placed on a mild heating surface, and packed round with the cocoa-nut fibre, the heat would be retained about them.

Pinus Austriaca (*O. H.*).—This will withstand wind well—so well, that it is one of the best Conifers for planting near the seashore. For high exposed places it would do well on the south side of a mountain, but unless the soil were of fair depth on a hill side, we would not plant it in preference to the Larch or the common Scotch Fir. The heartwood of Pinus austriaca is red, firm, resinous, and enduring.

Iron Stove (*Idem*).—The main parts of your plate-iron stove are right. If the stove become hot enough we have no fault with the sand at the sides. The great object should be to concentrate the heat in the stove, and not to send it into the smoke-pipe. Your smoke-pipe is opposite the furnace door; in fact, rather below it. It would have been better if the smoke-opening had been as near the top as possible, and then the heat would have struck against the top and sides of the stove before finding such an easy exit. As you have too much heat in the pipe, and the fuel burns too rapidly, you would lessen draught and economise fuel by having a strong flat piece of iron 5 inches square, kept in position 1½ inch in front of your smoke pipe. Two iron spikes could go into the smoke-pipe to keep it in its place. Meantime try what partly blocking-up your smoke-pipe will do, by reducing it one-half with a piece of brick. Your great error, however, is in having furnace and ash-pit doors not fitting closely. When such a stove as yours is heated, and you merely wish a slow combustion to keep up a mild heat a long time, something like one-eighth-of-an-inch opening in width, by 1 inch in length, in the ash-pit door, will be sufficient. On lighting and until the fire gets hold, air must be given, and the smoke-pipe will become hot; but when you shut up and reduce the air to very little, the pipe will soon cool 4 or 5 feet from the stove, whilst the stove will remain warm. With so little air the stove will keep warm after the fire has burned out. Before making the alterations in your doors, just try, after the fire is fairly burning, what a little air for draught will do, by daubing-up all the openings with stiff clay or dough, except such a small opening as referred to above, in the ashpit-door.

Peach Tree for a Cold House—Plum Trees Unfruitful (*A New Subscriber*).—We would recommend the Bellegarde Peach for your cold house, and Elruge or Violette Hâtive Nectarine for the back wall. The Plum trees to which you refer, planted eight or nine years, that bloom profusely but do not fruit, are a more intricate affair. As you have found the roots of one tree 1½ foot deep, that might be the reason, if the wood is strong and imperfectly ripened. If so, lifting and replanting near the surface would be the remedy; but if the wood is short-jointed and well ripened, and the blooms when examined seem perfect, we should conclude that the trees were suffering from poverty or want of moisture, and therefore we would make holes and water, and then surface-mulch. From what we have said you will be able to judge. If the trees do not grow strong and the roots are as deep as you say, we would, in preference to raising and replanting, remove a part of the surface soil and mulch.

Figs Bursting (*Anxious*).—When Figs are to be used at home we never mind, for we rather like to see them cracking, and their rich amber juice beading out. When the bursting is more than this, it is generally the result of drenching with water after comparative dryness.

Vines in Ground Vinery (*Amateur*).—All things considered, the Vines in ground vineries being so strong and healthy, we would let them alone for another year, as most likely the shanking was owing to want of water last summer. We would surface-mulch and keep the surface moist after growth had commenced.

Time for Pruning Vines (*Idem*).—Vines may be pruned as soon as the wood is ripe and the leaves begin to fall and change colour. A Vine several years old, like yours, should not be cut close into the stem, but to a spur, leaving one or two buds at the base of this season's growth. As respects a shoot of this season's growth, it should be shortened, and all laterals cut off, leaving only the buds—that is, supposing the fruit is to be produced on that young shoot next summer.

Sowing Grape Seeds (*Idem*).—To raise plants from Grape seed, the seed should be separated from the pulp when the fruit is perfectly ripe, washed, dried, and kept in a cool, dry, dark place until March, when it should be sown, covered thinly with soil, and the pot placed in a mild hotbed, the seedlings being pricked-off into small pots as they appear. Unless the flowers of the Grape were cross-fertilised, there would be little use in raising from seed.

Ripening Tomatoes Artificially (*Idem*).—Tomatoes, full-sized but green, will ripen in the kitchen screen, or any warm place. Cold and wet will cause them to blotch and rust.

Pruning Vines (*W. W.*).—The only object of leaving two buds instead of one on a spur of a Vine in a ground vinery is that thus you have a double chance of obtaining a fruitful shoot from the same joint. Leaving both shoots if they both showed fruit, would depend on how the other joints showed fruit. In general it would be advisable to leave only the shoot with the best show, and rub off the other one, choosing, if possible, the shoot nearest the main stem. This spurring system is the easiest, but some succeed best with rod-training—that is, when the Vine is established, shortening every bearing side shoot to one joint beyond the bunch, training a young shoot from the base to fruit next year, and cutting away the old one, just as you do with Raspberries.

Pears not Fruiting (*Idem*).—We think the Pears in the pots which have not set must either have been too wet or too dry, when Peaches and Plums set so well. Pears require more direct air when in bloom than Peaches, but they do well with similar treatment to Plums.

Grapes Red and Acid (*Half Pay*).—We suspect this is chiefly owing to the fact that the Vines have borne such a quantity of Grapes. Most likely if you had left only a half or two-thirds, the Grapes would have been all right. If, as a neighbouring gardener says, there is much red spider on the Vine, and very likely he is right, then, if much infested, that would to a great extent account for the bad condition of the fruit. We are more inclined to think he is right, as the Peach leaf sent, though we found no insect on it, showed that it had been well punctured by the little red spider. If the Vine leaves have the same greyish dotted appearance as the Peach leaf, there would be no doubt about it. If the leaves of the Vines are at all green, and the wood not well ripened, you must not think of burning sulphur in the house as advised. That can only be safely done with deciduous plants when in a state of rest and the wood thoroughly ripened, and therefore it requires judgment and experience. Besides, as the Grapes are now thin, the remaining bunches may be better, and it would be a pity to lose them. The red spider when full grown resembles in size the smallest grain of red sand, and can be easily seen by young eyes on the under side of the leaf. Wherever you see that grey-dotted spotted appearance as on the Peach leaf, you may be sure that the little enemy is present. If, in addition, you see pieces of foliage having a shining oiled-paper-like appearance, you may be sure that the jumping thrips is with you—a small insect, not more robust, but much larger than the red spider, and as difficult to eradicate. We may here say, in passing, that the midrib of your Peach leaf showed marks where scale had made a home for itself; one leaf of the Vine would have made us more certain. From what you state, the only way you can use sulphur now is as follows:—Shut the house or houses up by three o'clock. Then take some large pots, say 12 inches in diameter, fill them about half full with quicklime, pour on enough of water to slacken and saturate it thoroughly, and then sprinkle over each pot about 1 oz. of sulphur. For a house 30 feet long and 10 feet wide we would use two pots. In the morning, syringe freely where there is no fruit. This, with less sulphur, is a good preventive in summer. This is very different from burning sulphur. When the lime is very strong use less sulphur. At this advanced season, however, your main remedy for next season would be, as soon as the leaves fall, or are removed, to wash everything in the house, as well as the trees, with soft-soap water at fully 150° to 160°, and then paint the trees with weak Gishurst, or a paint of clay and sulphur, using the syringe pretty freely next season after the fruit is set, or weak sulphur fumes from hot-water plates, or other surfaces not hotter than 160°. See "Doings of the Last Week" lately.

Planting Vines—Border—Vines in Pots (*T. J. M.*).—As you are only now making your border, we would allow it to settle until March before planting, so that there will be no risk of straining or cracking the roots. The brick rubble at the bottom of the border is all right enough, but that will not be sufficient unless you have a drain besides, if there is the least chance of stagnant water. The reversing of the green sods over the bricks is all right, but the garden refuse we should consider the worst material you could use, and the most likely to produce mildew at the roots. A mixture of soil, half-inch bones, and oyster shells, is quite right; say five or six bushels of the former, and ten of the latter, for your size of border, but one-third of dung would be out of place; one-twelfth

or one-fifteenth of sweet rotten material would be nearer the mark. The large Vines in pots that showed well but refused to set, failed most likely from want of drainage, or want of enough of moisture at the roots, and enough of heat and air at the time. Such four-year-old Vines are not much better than younger ones for planting out. In planting, the roots should be gently disentangled and spread out regularly on the border, packed nicely, watered with warm water, and covered with from 6 to 8 inches of nice soil; then, if you place 6 inches of warm dung on the surface, and cover with the glass as you intend doing, the roots will begin to work at once before the buds begin to swell. The Vine two years old in a pot, and so strong and well ripened, will fruit best in the pot. Pick out an inch or two of the surface soil, replace it with rich compost, water gradually until the soil is well moistened before the buds break, then set your pot near the flue. As it is 10 feet long, we would cut away 2 or 3 feet, and the remainder we would twist round three or four sticks. We have often done so with Vines as long as yours, if well ripened for that length—10 feet. The twisting round in open cylinder shape caused the buds to break more regularly. Then you could reserve the best and strongest shoots, and rub off those not wanted. If you take a heavy crop the first season, the plant will do little good afterwards.

Mildewed Vines (*North Norfolk*).—Flowers of sulphur scattered early over leaf and berry is the most effectual remedy, and if sulphur is painted on a heating medium that is not hotter than from 160° to 170°, it would greatly help to banish the pest. If your house is now empty—that is, if there is nothing growing in it, and the wood of the Vines is brown and firm, you might burn a little sulphur in the house; but unless sure of the hardness of the wood, do not attempt it, as it will kill everything green, or at all unripe. Your chief remedy must be a thorough washing of every part of the house, Vines, &c., with warm soft-soap water, whitewashing, or rather limewashing the walls, using a good portion of sulphur with the lime, and then painting the Vines rather thickly over with a paint made of clay, sulphur, and soft-soap water. The sooner this is done the better, as the longer the paint remains on the shoots and stems before the Vines break, the more effectual it will be. Next season, wherever the sun will beat on the walls paint them with sulphur, and use sulphur on the heating medium if not above 160°.

Pruning Pleroma elegans (*K. M. B.*).—The plant, being old and leggy, will not do well if cut down to within 6 or 7 inches of the root, as it may not shoot freely from the old hard wood. You may, however, cut it well in next year after flowering, putting in cuttings of the young shoots, after they become firm at the base, in sandy peat, covering them with a bell-glass. If you have shoots near the base, with dormant buds or eyes, you may cut the plant down in April, keeping it dry for about a fortnight, and yet keeping the soil moist, and when it has made shoots a few inches long repot it, disrooting and potting in a pot of smaller size, watering carefully until the roots are working freely in the fresh soil. Young plants would, however, serve your purpose better than an old plant that is tall and scraggy.

Manetti Stocks (*E. W.*).—You may pot the plants or stocks, and get them in January or February, the pots being plunged in a hotbed, or you may plant them out and bud them in July. Rivers's "Rose Amateurs' Guide" will suit you. It contains particulars of Rose-propagation. We do not know the plant from the sprig sent. Flowers and a better specimen are needed.

Sipho campylus Humboldtii Culture (*W. E.*).—Being from Peru, it requires a greenhouse. Keep it rather dry in winter, giving no more water than enough to keep the plant fresh, repot in spring when the plant begins to grow, reducing the ball, and potting in a size of pot no larger than sufficient to hold the roots comfortably. Keep it shaded and moist, avoiding over-watering at all times, but especially immediately after repotting, and when recovered from the potting expose it fully to light and air, assigning it a position near the glass. What pruning is needed ought to be done before the plant begins to grow. Pot into the blooming pot when the other pot is filled with roots, and do not give a large shift, as the plant when largely potted grows too much to wood. Train the shoots as required, to promote a compact, well-shaped plant. Syringe freely to keep down red spider. Good drainage is necessary, as when the plant is growing, an abundant supply of water is needed. A compost of two parts fibrous sandy loam, one part leaf soil or sandy peat, with a free admixture of sand, will grow it well.

Tacsonia Buchanani (*Idem*).—It would not succeed on the back wall of a stove, or even on the end. A greenhouse is more suitable, the shoots being trained moderately thin, and near the glass.

Anthurium Scherzerianum (*Idem*).—The Cucumber house would be a better place for this than the stove at the night temperature of 55°, though in such it would succeed if that temperature occurred only on cold nights.

Gooseberries (*J. Whalton*).—There is no book on growing Gooseberries for exhibition. Any bookseller could obtain for you the numbers of this Journal that you need to complete your set, if you let him know those which you have.

Lessee Removing Fruit Trees (*A.*).—We think that if you potted the trees now you might take them away when you vacate the premises at the end of three years, but the point has never been decided.

Names of Fruits (*W. Dalley, jun.*).—1, Glou Morceau; 2, Beurré Diec.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending November 16th.

Date.	Barometer.		Thermometer. Air.		Earth.		Wind.	Rain in inches.	General Remarks.

POULTRY, BEE, AND PIGEON CHRONICLE.

OUR POULTRY SHOWS.

"Aliquis" complains that I do not state in what the evil named in my letter of October 21st consists. It simply consists in the amount of dissatisfaction and distrust it engenders in the minds of absent exhibitors.

I have had considerable experience in the exhibition of poultry, and I have ever found that where an official of a show has taken the lion's share of prizes, a great deal of dissatisfaction has been expressed, even by exhibitors present; and therefore I am of opinion that secretaries and committeemen would better subserve the interests of the show with which they are connected, by refraining from competing for prizes altogether.

I have known "enthusiastic fanciers" refuse to act on committees in order that they might be exhibitors, and instances are not wanting in which large exhibitors have, for the benefit of their local show, refrained from competing for prizes, although they have allowed their birds to be exhibited, but had labels attached "not for competition."

I must pass over the enloginms "Aliquis" chooses to pass upon secretaries, committeemen, and the "lady" who wrote out "copy for the printer" as totally irrelevant to the question at issue, but I have always been led to suppose that honorary secretaries and committeemen "were willing to spend and be spent for their particular hobby" without fee or reward, either present or prospective. It appears that "Aliquis" thinks differently, for he asks "Why all this labour and expense?" Is it simply to bring birds from a distance to compete for their prizes? By no means, says "Aliquis." What in the world is it for, then? Let "Aliquis" answer. "It is to bring a great show home to their own doors." What for? "Aliquis" tells us, in order that "they may measure with their own eyes the produce of their own yards, &c, with those of their friends afar off." Now, it is sheer madness to suppose that any exhibitor, however affluent and exalted his position, stocks his yards with valuable bird purchased sometimes at fabulous prices, pays large entrance fees, subjects his pets to a long journey by railway, and sometimes to neglect and rough usage at the hands of officials or their employés, simply to afford local exhibitors and committeemen whom he has never seen, an opportunity of "measuring with their own eyes," &c. Anything more preposterous than this it is difficult to imagine.

I cannot agree with "Aliquis" that local prizes are given "on the assumption that the local man has but a small chance with the outside competitor." Indeed, the facts are directly against him, as is witnessed by the awards at the show to which I alluded; and I am also at a loss to understand his meaning when he says he cannot see any evil likely to result from the second complaint, when, directly after, he says, "I am quite open to admit that in offering a local cup, the contingency I have supposed (viz., a local exhibitor taking both the local and general cups) is not contemplated, and will not often occur; in fact its frequent repetition would defeat its original intention," &c. Here again "Aliquis" turns the tables upon himself, and strongly advocates the abolition of the system of which I complained, for we find this very "contingency" occurring twice at the same show.

Just a word or two in reply to "Gloucestershire," and I have done. I am sorry to say he is in many cases sadly mistaken respecting the competency of the men appointed to

handle the birds, &c., for the judges, for I have stood by when exhibitors have been allowed to witness the judging (which I think should be done where practicable), and seen valuable birds seized by the leg, the wing, and not unfrequently by the neck, and handed to the judge for examination. Competent persons ought to be appointed, but by no means ought these persons to be "local exhibitors" or committeemen who have birds in the show at which the judges are making their awards. —JUSTICE.

"EGOMET'S" tilt at "ALIQUIS" in "our Journal" of November 11th, is far more amusing than instructive. His fine burlesque, and the introduction of his French and Latin, do not explain to the poultry world how he would meet the chief question, or point out the way to induce committeemen to do all this finger-blistering, &c., without that "*quid pro quo*"—a fair chance of the prizes.

Now, "EGOMET" may be inspired by the best intentions. Knaves are to be found among all classes of men, and committeemen cannot claim exception to the rule. No harm can be done by being watchful and vigilant, checking all real abuses as they crop up, in or out of committee; but whenever the attempt is seriously made to entirely prohibit all those connected with shows from exhibiting, exhibitions generally must decline. A line must be drawn somewhere; if it be drawn too tightly it will snap. If committeemen are not to exhibit at their own show, poultry in a short time will be shown only in connection with cattle shows, few and far between; then farewell to the advanced breeding of our pets, and the "*quid pro quo*" of—AN OLD COMMITTEEMAN.

LONDON POULTRY SHOW.

IT will be seen in our list of poultry shows that this, to be held at the Crystal Palace, will commence on the 22nd of January, 1870. The money prizes much exceed £300, besides which there are more than twenty silver cups and other extra prizes. We know that many breeders of French fowls and others wish to subscribe for extra prizes, and they should promptly communicate with the Secretaries.

DESTROYING THE VITALITY OF EGGS.

IN "Letter Box," page 372, "HENWIFE" is answered—"We believe there is no certain mode of destruction, unless you spoil the eggs for breakfast purposes."

I believe there is a certain method of destruction—viz., to put the eggs in boiling water for half a minute, or even a minute. This does not destroy their use for breakfast as boiled eggs. It may not be known to all your readers, but it is, nevertheless, a fact, that an egg may be boiled for three minutes, morning after morning, for any number of times without making it any harder than it was on the first day, so that the uneaten eggs of one morning are quite fit for the breakfast-table on the following morning, and I doubt if any one would detect a difference if the second boiling were "unbeknown." The half-minute's boiling would make a layer of coagulated albumen inside the shell, and I imagine if it does not destroy the germ of life altogether, it must be an effectual barrier to the escape of any chicken.

The eggs, I suspect, would scarcely look as well for poaching, as some portion of the white would remain in the shell. —Y. B. A. Z.

SOUTHAMPTON POULTRY AND PIGEON SHOW.

As far as the number of entries was considered, as well as in the good quality of almost every pen entered for competition, the recent Southampton Show was unequalled, and it is a matter of regret that neglect on the part of some individual should have marred in any way a success that would otherwise have been almost without parallel. Boylike, there seemed to be a strong tendency to shoulder the blame from one to another; but we believe the correct statement to be the following. It appears to be admitted, without dispute, that early and direct engagements for the necessary pens were entered into by the Committee with Messrs Turner, of Sheffield, a fully sufficient number being specified. The representative of Mr. Turner asserts, "that the whole engaged number left for Southampton by rail a week previous to the day appointed for fixing them." Parties from the railway give the contrary version. Be the fault where it may, the Southampton Committee and all connected with the Show were alike sufferers. So many pens being short, a large number of the wire-tops were cut from some of the upper tiers to make fronts for those pens deficient, whilst the pens that were divested of their wirework tops had to be covered with loose boards, which was a change anything but advantageous or desirable. The result was, that again and again, during the arbitrations, the sole Judge found himself compelled to "hark back" class after class, because the whole of the pens of this or the other variety were either not begun or only in course of erection. This unexpected delay caused the awards not to be completed till between two and three o'clock in the afternoon of the day of opening, and even then but a very few of the prize cards were affixed to the winning pens. The absolute loss to the Society in reference to the sale of birds that might otherwise have been effected of course can never be ascertained, whilst the vexation entailed on the worthy and indefatigable Secretary Mr. Philip Warren, was indeed ill-deserved, for, as was observed on the spot by several amateurs, "the Southampton Show on all former occasions had gone on like clockwork." To enter into any farther detail of the identity of the responsibility in this affair we do not purpose, but perhaps a passing word may prevent the recurrence of such neglect and disappointment. We suggest it would be well in all agreements for the hire of show pens, to directly stipulate that the non-fulfilment of the contract from any cause whatever should entail on the parties supplying the pens the fine of £20. This would certainly make them especially careful as to the promptitude of the railway transit, and the erection of the pens on arrival. As we are unable to give many particulars respecting the quality of this really excellent Show, it may be as well simply to state, in justice to Messrs. Turner, that their new pens show a great improvement on the original ones so long known and so well encouraged. The present pens are wrought out of much thinner wire, though being well galvanised they are quite strong enough for any poultry, and as the wirework is closer, fighting of any kind is an impossibility. The fowls are more easily inspected, and the weight of the pens is so much reduced that the carriage from place to place is now merely nominal.

Some of the most remarkable classes were the *Brahmas*, both Light and Dark ones, the *Game Fowls*, *Dorkings*, *Turkeys*, and *Geese*. Of the latter, a pen of Sebastopol Geese, the most perfect yet exhibited, were entered. In the "Variety class" for fowls, a pen of fowls entered as "Gangesian," were evidently a new variety, being white, of very large size, throated and whiskered to an unusual extent. They promise to be a valuable addition to our domesticated poultry. The weather was exceedingly fine, and the attendance of visitors was particularly good. We gave last week a list of the prizes, and now append that of the commendations.

SPANISH.—*hc*, P. H. Jones, Fulham. *c*, C. F. Hore, Tunbridge.

DORKINGS.—*hc*, Viscount Turnour, Shillinglee Park; Dr. D. C. Campbell, Brentwood. *c*, H. R. Seymour. *Chickens.*—*hc*, J. Smith, Shillinglee, Petworth; O. E. Cresswell, Hanworth Rectory; J. Martin, Claines, Worcester; L. Patton, Hillmore, Taunton. *c*, Mrs. M. D. Dunn, Inglewood, Hungerford; J. Chisman, Rowuhams, Southampton; J. Hodgkinson, Southampton.

COCHINS (Any variety).—*hc*, Mrs. A. Williamson, Queniborough Hall, Leicester; W. Cole (Partridge); Capt. T. S. Robin, Fontenay, Jersey; H. Lingwood, Needham Market; W. N Scott (Buff); F. W. Rust, Hastings (Buff). *c*, T. M. Derry, Gedney (Buff); F. W. Rust (Buff).

BRAHMAS (Dark) —*hc*, J. Chisman; Rev. R. Parker, Wykeham Rectory, Fareham; W. Sims, Stroud. *c*, T. S. Robin.

BRAHMAS (Light .—*hc*, F. Crook, Forest Hill; Mrs. S. Vigor, Uxbridge; H. Dowsett, Pleshey, Chelmsford. *Chickens.*—*hc*. Mrs. A. Williamson; F. Crook; H. M. Maynard. *c*, J. Chisman; Mrs. Pattison, Wrackleford House, Dorchester; H. M. Maynard; J. Pares, Postford, Guildford; H. Dowsett.

GAME (Black and other Reds).—*hc*, W. H. Stagg, Netheravon, Amesbury; S. Matthews, Stowmarket; R. Hall, Cambridge. *c*, H. Loe; J. Jeken, Eltham; H. C. Dear, North Stoneham. *Chickens.*—*hc*, Rev. T. O'Grady, Hognaston Vicarage, Ashbourne; H. Gibson, Brockenhurst; S. Matthews. *c*, W. H. Stagg; H. Loe, Appuldurcombe; S. Matthews; H. C. Dear.

GAME (Other variety).—*hc*, W. Shenton, Worcester; S. Matthews.

HAMBURGHS (Silver and Gold-pencilled).—*hc*, J. Toll, jun., Cartuther Mills, Menheniot; R. Folton; S. & R. Ashton, Mottram; E. Brierley, Heywood, Manchester. *c*, Mrs. Pattison; F. Pittis, jun., Newport Isle of Wight; H. Pickles, jun.

POLANDS.—*hc*, G. Boothby, Louth, Lincolnshire.

FRENCH. — *hc*, H. M. Maynard (Houdans); J. Malden, Biggleswade, Faversham (Crève-Cœur); W. Dring (Crève-Cœur). *c*, Capt. T. S. Robin (La Flèche); W. Tippler, Duke's Roxwell, Chelmsford (La Flèche).

HOUDANS.—*Chickens.*—*hc*, Mrs. L. Paget, Wimborne, Dorset. *c*, Hill and Co., Brighton; W. O. Quibell, Newark; P. D. Maddox, Launceston; J. H. Dawes.

ANY OTHER VARIETY.—*hc*, J. Hodgkinson (Indian Pheasant).

GAME BANTAMS.—*hc*, H. Loe; A. Stonar, Peterborough; J. W. Kellaway, Mers'on, Isle of Wight.

BANTAMS (Other variety).—*hc*, Lady S. Turnour, Shillinglee Park (Japanese); Countess Winterton (Gold-laced); H. Pickles, jun., Earby, Skipton (Black). *c*, T. C. Harrison.

DUCKS (Aylesbury).—*hc*, Major-General H. P. de Bathe, Chichester; R. Fulton; W. Tippler. *c* G. Colmer, Southampton.

DUCKS (Other variety).—*hc*, L. H. Ricketts (Rouen); F. Pittis, jun. (Black East Indian); Mrs. Morant, Brockenhurst Park (Carolina); H. Dowsett (Rouen); C. F. Hore (Rouen . *c*, Major-Gen. H. P. de Bathe (Black Rio); Mrs. Turner (Muscovy); J. Toll, jun. (Rouen).

GEESE.—*hc*, Mrs. M. Ford, Weymouth (Toulouse); Lady Heathcote Winchester (Toulouse).

TURKEYS.—*c*, Major-Gen. H. P. de Bathe (Almond); J. E. Stubbs.

SELLING CLASS.—*Cock or Cockerel.*—*hc*, Viscount Turnour (Dorkings). J. Smith (Dorkings); H. M. Maynard, Holmewood, Ryde Brahma); S Samways, Lymington, Southampton (Brahma); R. Pople, West Moulsey (Dorking); S. & R. Ashton, Mottram (Golden-spangled); T. Rogers, Walsall. *c*, Capt. T. S. Robin (Breda); H. M. Maynard (Brahma); Mrs. Morant (East Indian); Hill & Co. (Houdan); W. Stanford, Steyning (Dorking); T. J. Saltmarsh (Partridge Cochin). *Hens or Pullets.*—*hc*, Mrs. M. D. Dunn, Ioglefoord, Hungerford (Dorkings); J. Chisman (Dorkings); Mrs. Malcolm, Beechwood, Totton (Dorkings); Lady S. Turnour (Japanese Bantam); H. M. Maynard (Houdans); Mrs. Bornaby, Nursling Mount, Southampton; Miss J. Millward, Newton St. Loe, Bristol (Cochins). *c*, J.

Chisman (Dark Brahmas); Rev. N. J. Ridley (Crossbred); Lady Heathcote (Houdans); F. Crook (Brahmas); Viscount Turnour (Dorkings); H. M. Maynard (Brahma); H. Loe, Appuldurcombe; W. Stanford, jun. (Game); F. Brewer, Lostwithiel (Houdans); J. R. Rodbard (Cochins).

PIGEONS.

Pouters.—*hc*, R. Fulton, Duke Street, Deptford; J. Hawley, Bingley. *c*, P. H. Jones, Fulham.
Tumblers.—*hc*, J. Lufkin, Farnham. *c*, P. H. Jones; C. Bulpin.
Barbs.—*hc*, H. M. Maynard; J. Hawley.
Jacobins.—*hc*, C. Bulpin. *c*, P. H. Jones.
Fantails.—*hc*, M. A. Vetts, Reading; Rev. W. S. Shaw, Bath; S. A. Wyllie, East Moulsey; J. F. Loversidge, Newark; J. Hawley. *c*, Rev. W. S. Shaw.
Owls.—*hc*, S. Wyllie; H. J. Kelsey. *c*, H. Hawley.
Turbits.—*hc*, J. C. Ord; R. Fulton; J. Hawley. *c*, J. Hawley; C. Bulpin.
Carriers.—*hc*, R. Fulton; W. Bishop, Dorchester. *c*, J. Lufkin.
Trumpeters.—*hc*, C. J. Spary, Ventnor; W. H. Cooper, Farnborough; P. H. Jones; C. Bulpin.
Nuns.—*hc*, C. Bulpin.
Dragoons.—*hc*, W. Bishop; C. Bulpin; H. Yardley; J. Hawley.
Any other Distinct Variety.—*hc*, Capt. T. S. Robin (Blue Runts); H. Yardley; W. S. Soder (Toys); J. Hawley. *c*, J. C. Ord (Hyacinths); H. Gibson (Yellow Magpies); S. A. Wyllie (German Spots, Ice, and Austrian Pouters); W. B. Ford (Antwerps); P. H. Jones; W. S. Soder (Frillbacks).
Selling Class.—*hc*, F. Pittis, jun. (Magpies); W. B. Tegetmeier, Finchley; W. S. Soder (Fantails and Toys); J. Hawley. *c*, H. M. Maynard (Carriers); J. C. Ord (Carriers); F. Pittis, jun. (Magpies); Miss J. Millward (Antwerps); P. H. Jones; E. Sheerman, Chelmsford.

CANARIES.

Norwich (Clear Yellow).—*vhc*, Bemrose & Orme, Derby; W. Walter, Winchester; Irons & Gayton, Northampton; J. Bexson, Derby; Moore and Wynn, Northampton. *hc*, W. Walter; H. Apted, Broadwater; Irons and Gayton. *c*, E. Lidstone, West Cowes; W. Walter; O. Nicholson, Landport.
Norwich (Clear Buff).—*vhc*, E. Hawkins, London; Irons & Gayton; J. Bexson; Moore & Wynn; O. Nicholson. *hc*, W. Walter; F. Hodding, Salisbury; Widdowson & Holme; H. Vine; H. Apted; T. Mann. *c*, G. E. N. Rawlinson; J. Bexson.
Norwich (Marked or Variegated Yellow).—*vhc*, Bemrose & Orme; W. Walter; Moore & Wynn; O. Nicholson. *hc*, Bemrose & Orme; Irons and Gayton; T. Mann, Camberwell New Road, London. *c*, Bemrose & Orme; J. Bexson; H. Apted.
Norwich (Marked or Variegated Buff).—*vhc*, Moore & Wynn; Widdowson & Holmes. *hc*, J. Bexson; H. Apted, Kettering; W. J. Toon. *c*, W. Walter; Irons & Gayton; O. Nicholson.
Norwich (Any other variety).—*vhc*, Irons & Gayton; Moore & Wynn. *hc*, H. Apted. *c*, O. Nicholson.
Belgian (Clear Yellow).—*vhc*, O. Nicholson; Widdowson & Holmes.
Belgian (Clear Buff).—*hc*, O. Nicholson; Widdowson & Holmes. *c*, E. Hawkins.
Beglian (Variegated or Marked Yellow).—*hc*, Widdowson & Holmes.
Belgian (Variegated or Marked Buff).—*hc*, Widdowson & Holmes. *c*, J. Hayes.
Lizard (Golden-spangled).—*vhc*, E. Hawkins; Rev. V. Ward, Canterbury. *hc*, Mrs. W. C. Drummond, Bath; J. Hayes. *c*, T. Fairbrass, Canterbury; Rev. V. Ward; O. Nicholson.
Lizards (Silver-spangled).—*vhc*, E. Hawkins. *hc*, O. Nicholson. *c*, Widdowson & Holmes.
Goldfinch Mules (Mealy).—*hc*, Rev. V. Ward.
Skylark.—*vhc*, O. Nicholson.
Woodlark.—*vhc*, W. Walter.
Blackbird.—*vhc*, T. J. Townsend, Lower Norwood; T. Webb.
Song Thrush.—*vhc*, H. Carter, Southampton.
Cockatoo (Any variety).—*vhc*, W. Walter (White).
Pheasants.—*hc*, W. Stead, Romsey.

BIRMINGHAM PHILOPERISTERON SOCIETY'S SHOW.

The third meeting of the Birmingham Philoperisteron Society, held on the 11th inst. at the Athenæum Hall, proved most successful, and in every respect surpassed the two former shows. The Carriers formed large and excellent classes, and from their general perfection drew much attention. In Pouters, unquestionably the White ones, of which there were some half-dozen pens, would have added much to the credit of any meeting. The winning Almonds were well worthy of the silver cup, and had travelled from Beverley to compete. Fantails proved very large classes, and among them were many, both Blacks and Blues, that were far beyond those generally shown. Dragoons always a strongly filled class, and Antwerps, which seem to be equally great local favourites at Birmingham, well repaid careful examination. A somewhat unusual entry was made by Mr. Yardley of three varieties of fancy Pigeons—viz., Barbs, Carriers, and Almonds, shown in very large cages, each containing twenty first-rate specimens of the respective varieties. A grand pair of Swift Pigeons from Egypt were objects that from their extreme rarity excited considerable attention, and secured for the owner one of the five silver cups that were offered for competition.

The general arrangements of the Show were satisfactory, and the Judges for all the fancy Pigeons were Mr. Hewitt and Mr. Yardley; and the Judge for flying Pigeons was Mr. Beardmore.

YOUNG BIRDS.

Carriers.—1, J. Smith, Birmingham. 2 and 3, J. Wood, Derby. 4, F. F. Foster, Birmingham. *hc*, J. F. While, Birmingham.
Pouters.—1 and 2, G. Sturgess, Leicester. 3, F. F. Foster.

Badges (Any other colour).—1, H. Clulee.
Saddles (Black).—1, 2, and *hc*, H. Sproston.
Saddles (Blue).—1, H. Clulee.
Rosewings and Redbreasts.—1, A. Walthew.
Tumblers (Any other variety).—1, A. Walthew.

STOKESLEY CANARY SHOW.

"When you arrive at Stokesley station, take the 'bus to the 'Black Swan,' where you will find breakfast waiting for you." Such was the kind intimation I received from Mr. Horatio J. Tweddell, the Honorary Secretary of the Stokesley Society; and after a cheerless ride on a cold, wet November morning, it commended itself to my judgment as a most happy arrangement. Indeed, when I found myself seated in a comfortable arm-chair beside the fire in the parlour of the "Black Swan" aforesaid, discussing the merits of Yorkshire ham and eggs, I voted the Judge's breakfast to be a right noble institution, well worthy of adoption by all kindred societies. I went into that hostelry a cold, damp, morose man, and left it a warm, dry, benevolent-looking individual, and as I wended my way down to the National Schoolroom, where the Show was held, I felt on remarkably good terms with myself.

The pretty little town of Stokesley was in a state of commotion, for besides being market-day it was the "hirings," and I passed *such* lonny Yorkshire lasses standing in the market-place waiting to be hired. The scene had the charm of novelty to me, and it was amusing to listen to some of the bargain-making between master and servant. I lifted up my head and put on my best looks, made the most graceful step which the lingering remains of a slight attack of lumbago would admit of, and gave just the faintest shadow of a cough as I passed any unusually attractive group; but it was all thrown away, and when I heard a suppressed titter issuing from the mouth of an Amazon whose "points" very much resembled those of the Canary most in vogue in Yorkshire—viz., 1st, large round head; 2nd, long straight neck; 3rd, broad shoulders; 4th, straight back, and well filled in; 5th, firm stand, and bold carriage, &c., I thought it was time for me to demean myself in a manner more befitting the sober dignity of the representative of "our Journal," and by the time I reached the show room I was in a proper frame of mind to pronounce on the merits of the birds, which were staged to the number of nearly three hundred.

Taking the Exhibition as a whole it was one of great excellence. Many of the best birds were at Darlington, and had obtained honours there, and any special mention of them now would be tedious; but I cannot pass Classes 14 to 18, the Yorkshire variety, without comment. The true Yorkshire bird seems either to be dying out, or is being lost sight of in the person of a mongrel, which, whatever it may be, is most assuredly not what it represents itself to be. One would say that in such a case the Judge's duty is very plain—to disqualify the

whole class, or at least those birds which bore impostor stamped on them. True; but this crossing with one variety and another to obtain colour, shape, or some other fancied excellence, has of late years become so much a matter of custom among the Yorkshire fanciers, as to have opened the door for a spurious species of judgment prejudicial to the best interests of the admirers of this really very pretty bird; and the awards at most of our shows, and also where I have assisted myself, have frequently been given to the fashionable modern bird rather than to the true type, till at last *colour* has become so much the rage, that large Norwich birds which have taken prizes as such have also been exhibited, and successfully too, in the Yorkshire classes. This has been done with the entire acquiescence of the fancy, each man getting his turn as the Judge admired his particular speciality or otherwise. This state of things, however, was sure to work its own cure, and I brought the matter to culminating point by awarding the prizes to specimens differing most widely in their characteristic features. Of course all the intermediate men were much disappointed, but the verdict was, "Served us right;" and I venture to predict I have done a real good to a most beautiful variety of the Canary—the true Yorkshire. To all whom it may concern I say, in prospect of Middlesbrough, Stockton, Thirsk, and elsewhere, Don't enter Norwich birds in the Yorkshire class, but put them in their right place, and give the others fair play. And to those who may be wishful to breed the Yorkshire variety in its purity, I would say, It requires no admixture of the Jonque, for that is not its legitimate colour, nor is the shape and carriage of the Norwich Canary that of the Yorkshire.

Goldfinches, Linnets, and British birds generally were well represented, and there was the prettiest collection of foreign birds I have seen for some time.—W. A. Blakston.

Belgian (Yellow).—1, J. N. Harrison, Belper, Derby. 2, W. Needler, Hull. 3, R. Robinson, Middlesbrough.

Belgian (Buff).—1, W. Needler. 2, R. Robinson. 3, J. N. Harrison.

Norwich (Clear Buff).—1, Pennock & Blackstone. 2, R. Simpson, Whitby. 3, Moore & Wynn.

Norwich (Yellow, even marked).—1, E. Mills, Sunderland. 2, Moore and Wynn. 3, J. Bexson, Derby.

Norwich (Buff, even marked).—1, G. Gayton, Northampton. 2, Pennock & Blackstone. 3, J. Young, Sunderland.

Norwich (Yellow or Buff, uneven marked or ticked).—1, R. Hawman, Middlesbrough. 2, Pennock & Blackstone. 3, J. Bexson.

Don (Cinnamon).—1, T. Irons. 2, J. Bexson. 3, Moore & Wynn.

Dun (Buff).—1, J. Bexson. 2, T. Irons. 3, J. Young.

Lizard (Golden-spangled).—1, T. Standfield, Stockton. 2, W. Needler. 3, Pennock & Blackstone.

Lizard (Silver-spangled).—1, R. Hawman. 2, S. McKew, Stockton. 3, J. Taylor, Middlesbrough.

Canary (Dark or Grey-crested).—1, T. Irons. 2, T. Armstrong, Broughton. 3, Pennock & Blackstone.

Canary (Yellow or Buff-crested).—1, W. Cotton, Middlesbrough. 2, T. Irons. 3, J. Garbutt, Broughton.

Canary (Clear Yellow Yorkshire).—1, M. Burton, Middlesbrough. 2, T. Armstrong. 3, J. Garbutt.

Canary (Clear Buff Yorkshire).—1, S. Hawman, Middlesbrough. 2, W. Mountain, Ayton. 3, Porritt & Raw, Ruswarp.

Yorkshire (Yellow, even marked).—1, J. Taylor. 2, M. Burton. 3, R. Hawman.

Yorkshire (Buff, even marked).—1, J. Taylor. 2, W. Needler. 3, M. Burton.

Canary (Yorkshire, uneven marked or ticked).—1, G. Garbutt, Broughton. 2, W. McLachlin, Whitby. 3, T. Whitelock.

Cage of Eight Canaries, not more than Two of each Variety.—1, R. Harker, Stokesley. 2, G. Garbutt. 3, E. Barker, Whitby.

Mule (Variegated Goldfinch).—1 and 2, J. Young. 3, R. Robinson.

Mule (Dark Goldfinch).—1, Moore & Wynn. 2, M. Burton. 3, J. Yates, Middlesbrough.

Canary (Clear Green).—1, M. Burton. 2, R. Fidler. 3, T. Teuniswood, Middlesbrough.

Goldfinch (Moulted).—1, W. McLachlin. 2, J. Young. 3, G. Garbutt.

Linnet (Moulted).—1, J. N. Harrison. 2, J. Young. 3, W. Maynard, Ingleby Manor.

Any other Variety of British Birds.—1, W. Simonson, Stokesley (Thrush). 2, S. McKew (Blackbird). 3, J. Cuthbertson, Stokesley (Bullfinch).

Any Variety of Foreign Bird.—1, T. Bailey, Sowerby, Thirsk. 2, T. R. Untbank, Stokesley (Parrot). 3, Miss Cheveley, Ingleby Manor (Madagascar Grossbeak).

Judge.—Mr. W. A. Blakston, Sunderland.

SATINETTE PIGEONS.

I trust you will give publicity to the facts which led to the remark in my advertisement in respect to the Satinettes. When I bought Mr. Noyé's stock, he expressed to me that "there were two pairs in the lot better than he ever had, including the best pair he exhibited at the Bingley Hall last year." This remark led me to the conclusion that it was the first-prize pair, and consequently I advertised them as such, and though it was a misunderstanding, I am perfectly satisfied that I possess the best two pairs he ever had.—H. Yardley.

Dublin Exhibition Palace Show.—In our advertising columns may be seen the time of the holding this exhibition, and whence to obtain full particulars, but we must observe that the prize list is most liberal. Prizes are given for poultry (including separate rewards for Houdans, Crêve-Cœurs, and La Flèches), Pigeons, cage birds, and even for cats. There are eighteen silver cups, in addition to the money prizes, which vary from £5 to 10*s*.

REVOLUTIONISING A HIVE.

Some time since, having introduced a stock of Ligurian bees into our apiary, we found that to keep the breed pure we must either banish all the old hives or else depose the queens, and as the stocks were very strong and in frame hives we determined to try the latter; and how we managed this is what I wish to convey to you.

Mr. Woodbury having kindly undertaken to procure six Italian queens, about the 10th of October we went over the same number of hives, and set right any of the combs which were not quite straight or confined to one frame. We then made half a dozen boxes, to receive the queens we had a design on, in the following way: They were about 4 inches square, and in the bottom we bored two three-quarter-inch holes 2½ inches apart, over which on the outside was fixed a strip of zinc with one tack, so as to open or close the holes easily. The top we closed with a piece of glass hinged to the box with a strip of linen and glue. Having fixed a piece of sealed comb we placed one of these over each hive, opening enough of space in the slide-in honey board to admit the bees through the holes before referred to. By these means we got all the loose honey cleared up, and the pieces of comb firmly fixed in their places, and we next day removed the boxes, none of the sealed cells having been opened. The boxes so prepared were kept until we were advised of the expected arrival of the foreigners, when about an hour before opening the hives to hunt for the reigning queens they were replaced on the hives as before, by which means we secured the proper quantity of bees to keep her company during her captivity. This search for the queen is the most difficult part of the work, and requires great care in examining each comb in order not to pass her over. It took us two days to find the six, as we could only open the hives during the warmest part of the day for fear of chilling the brood. As each queen was secured she was slipped into the prepared box through one of the holes in the bottom, and this can be done without the least risk of letting her escape; and all the boxes were then covered up with a board to keep out the light, and placed in a warm room. To capture the new queens we used a 7-inch bell-glass, and found it very easy to do so by removing the cover from the boxes as quietly as possible in a room with one window, and shaking the bees into the glass, over which we placed a board, and, on reversing it, in every case we found the queen in the cluster. Waiting until she was separated a little from the other bees, we shifted the glass so as to leave her outside, and put a wire cage (or pipe-cover) over her, and then slipped a small piece of paper under it, having at the same time enclosed two or three of the bees with the queen. Taking the cage and paper we placed it on the desired place on the comb taken from the hive which we wished her to rule over, and drawing away the paper forced the cage into the surface until its lower edge came in contact with the "partition wall," as instructed by Mr. Woodbury in your Journal; and having replaced the comb, left it until next day.* On opening the hives we found it was not safe to liberate the captives, so had to leave them until the day following, when they were all liberated and received as they should be.

In conclusion, I have only to say that by following Mr. Woodbury's directions in your Journal a novice will find it easy to ligurianise any stock in a frame hive; and the only point on which I would at all differ from him is the time of keeping the queens confined, which should be, I think, at least two days; but this may only apply to this time of year, when the bees are not so lively as in the early part.

I omitted to mention, that when the queens are all captured the Ligurian bees may be all shaken or swept into the bell-glass, and, being sprinkled with honey, may be added to any of the stocks by placing the cup glass over the hive, from which the slide has of course been removed.—Hibernian Bee.

SPURIOUS HONEY.

"A Manchester Man" makes some remarks in your issue of the 4th inst., relating to my letter of the 28th of October,

* We shall publish a drawing of the cage thus employed.

which are calculated to convey a wrong impression as to what I meant regarding "the shape and material of the hive having very much to do with the quantity and quality of honey collected." It is true it matters not whether a hive be round, octagonal, hexagonal, or square, the honey stored would be to some extent the same; nevertheless, it is a well-known fact, that honey gathered from the same sources and stored in different parts of the hive, will have quite a different appearance and taste, although it may all be collected within a few days. So, then, the construction, which is the shape, whereby we can regulate the hive in every emergency, thus preserving the purity of the honey and augmenting the store, is of great importance; besides which, a hive should admit of, and offer, every facility for manipulation, such as adding and diminishing space, ventilating, depriving, artificial swarming, queen-rearing, &c. Not so with the hive which he describes; neither are Tegetmeier's hives the best. The Stewarton hive with moveable bars and crown-board is much superior, and taking everything into consideration equal to the Woodbury hive, although the last-named may have the preference in consequence of the combs being all of one size, this hive being, in fact, the one which I myself use; but I work it upon the Stewarton principle, and have hives yet standing which still weigh 100 lbs., after having taken half a hundredweight of fine comb from each; and may I inform "A Manchester Man," if he wants figures to prove the superiority of hives, that I am acquainted with a bee-keeper who had this year fewer hives than he states Mr. Pettigrew to have had, and yet obtained no less than a ton of fine comb in supers, besides a considerable quantity of inferior quality?

Your correspondent says, "We Manchester men prefer the article which gives the largest and best result." And so do we who work on the Stewarton principle, but we do not grudge a few pounds at the first outlay, as the produce soon repays it. I regret that he did not succeed with the Tegetmeier hives, as the fault lay not in the material, but in the management. Had he adopted the plan that I recommended some time since, and which was described at the same time by Mr. Langstroth, a very high authority on bees, his hives would not have succumbed to internal moisture. Many people place too much stress on the material of which the body of a hive is made; they seem quite to forget that the most of the hive is surrounded with comb which is most impervious to change, and that it is the crown that is the most particular part. Nature alone suggests this. It ought, then, to be managed in such a way as to carry off all moisture. Whereas the hive described by "A Manchester Man" is quite opposed to all this, and to every principle of good management.

With reference to judging honey by tasting, fancy, say fifty different lots, what would a person's taste be worth by the time he got to the end of it? Or, say a merchant choosing from one hundred different samples of anything, if he had to taste it. I assure your readers, the best judge is one who by appearance, smell, and commonly the feel, can detect a good article.

"A Manchester Man" comes pretty near the truth when he says the stronger the stock the more workers there are, the more honey will be collected. Now, the hive for this is the Stewarton one; but he must not be carried away by the notion that a hive 16 by 12, is a large hive, thrice that size might be said to be a large one.—A Lanarkshire Bee-keeper.

P.S.—I have forwarded two samples of honey which have been pronounced by novices, and men of skill, such as Mr. A. Pettigrew, to be sugar, but which I consider to be as fine honey as I have ever met with. No. 1 is from Ligurian bees. No. 2 was gathered in the same locality but by black bees. I should like to hear your opinion, as I consider the Ligurian honey the better, also what you think of them.

[The honey in each pot is very pale, and look like a supersaturated syrup of refined sugar. That in the pot No. 1, gathered by the Ligurians, is the whitest and most solid. Each is an excellent specimen of honey, well-flavoured, but beginning to crystallise.—Eds.]

OUR LETTER BOX.

Weight of Young Turkeys (*H. B.*).—Much depends on the breed and feeding. If they are Cambridge, and the food meal or oats, with a few peas and beans, mixed with milk, we should expect the hens to weigh 9, the cocks 12 to 14 lbs. each, when nearly five months old. These would be birds that have never had a check, but have thriven all their lives. No bird ever reaches the top weight of its breed or class unless it is fed from the first with a view to that result.

Tardy Moulting of a Cochin-China Cock (*A. T.*).—The older Cochins grow, the greater difficulty they experience in moulting, and the longer the process seems to be about. At three years old the best days of a Cochin are over, and nothing but good living will carry your bird through. For a young bird we should advise cooling food, for an old one we advise stimulants. Give him ground oats mixed with milk, meat chopped fine, and eggs. He must not be without grass and fresh earth, and should be kept alone. You may give him some ale twice every day.

Lacing of a Silver-spangled Hamburgh Cock (*A Subscriber*).—It is a disputed point whether the wing should or should not be laced. Our own opinion is that it should be. Mr. Baily's book on "Fowls" gives the points.

Cockerel not Amatory (*Monthly Reader*).—The time of year has much to do with the apparent reluctance of the cock to attend to the hens. This inattention will probably increase rather than otherwise till after Christmas. It is not the less true that birds have their antipathies, likes and dislikes. The description you give of the dwindling chickens is that of crop-bound birds. This arises from improper feeding, especially feeding from troughs. Feed them sparingly, and supply them with grass; discontinue the rice. The coop should not be put on stones, but on earth. Fowls should never be on stones, boards, or brick.

Face of the Spanish Cockerel (*Spanish Cock*).—A Spanish cockerel at six months old is far more advanced in face than a pullet at nine; he has not always a "dead" white face, but it does not follow he will not have. He should have no red when he is shown if he is expected to win. No real judge will allow a trimmed Spanish fowl to appear in the prize sheet. Many are disqualified by it. Hairs may be removed from the face without detection, but the feathers from the base of the comb to the beginning of the face cannot be tampered with with impunity.

Lame La Flèche Cock (*A. D. C.*).—It is probable the lameness proceeds from weakness. If so, he will be in the habit of roosting on his knees. He will require to be well fed three times per day, and one meal should be stale bread steeped in ale. The other feedings should have no whole corn in them. Barley meal or ground oats, if mixed with milk so much the better, cooked meat chopped fine, and even eggs boiled hard and minced, are the best food for him, given a very little at a time. You must judge for yourself whether the patient is worth the trouble and the expense.

Silver-pencilled Hamburghs (*A Two-years-old Sub.*).—Refer to our advertising columns. Some were advertised last week. If you wish for very superior birds, write to some of the owners who took prizes with Silver-pencilled Hamburghs at the shows of which we publish the prize lists.

Eggs of Dark Brahmas (*G. E. Gettins*).—Write to some of the well-known breeders who advertise in our columns.

Barb Pigeons (*Columbarian*).—Write to some of those who have taken prizes with them.

Fantail Pigeons with Incased Tail Feathers (*L.*).—We have also found this to be the case very frequently during the present year with our most highly-bred and delicate birds, especially with the hens. The cause is delicacy of constitution; the cure, warmth and good nutritious food. Keep your birds in on cold damp days. With some of the incased feathers you may, when the sheath is sufficiently dry, peel it off, splitting it carefully with your nail, or a penknife's point, but only as far as it is quite dry. With our birds we have entirely changed the food, and make them (for Fantails are idle birds), come some distance to be fed, instead of feeding them in their house when the weather is fine and dry, being sure that exercise strengthens and does good to every biped, feathered or otherwise. But warmth has much to do with the cure, while damp weather or rain makes the sheath tough and prevents its drying and scaling off, as it will do in warm weather. Do not pull the feathers out, as worse will probably succeed.

Honey Dark-coloured (*G. Chapman*).—The dark colour of your honey arises from some peculiarities of the season, or in the pasturage, and may not occur again. It is said that honey collected from honey-dew is often very dark.

Bottle-feeding Bees (*Conservative*).—The pattern which you enclose is of too close a texture for covering the mouths of feeding-bottles. As stated in page 26 of the last edition of "Bee-keeping for the Many," as well as repeatedly in our columns, "it is a mistake to use muslin for this purpose, or, in fact, any material the meshes of which are less than a sixteenth part of an inch wide." With flat-topped hives where the aperture can be covered with perforated zinc, the only use of the net is to enable the bottle to be conveniently inverted. When this is effected, the net may be withdrawn altogether, as we have often done in the case of large wide-mouthed bottles when we wished to afford the bees every facility for taking food quickly. No other feeder is at all to be compared to the inverted bottle, and your question as to the food running through faster than the bees can take it up is founded on a complete but very common misapprehension. If properly managed, the bottle retains its contents by atmospheric pressure, on the principle of a bird-fountain. When once inverted and in its place, not a drop runs into the hive, but all remains perfectly suspended until removed by the bees. When, however, the bottle-mouth is tied over with material of too close a texture, the syrup appears so to clog the meshes that air cannot readily enter, and its surface assumes a concave form, which, when perforated zinc is interposed, withdraws nearly the whole of it beyond the reach of the bees' tongues, and the process of feeding under these circumstances becomes very slow indeed.

POULTRY MARKET.—November 17.

The supply is ample, and the trade bad. The late close weather has had a deadening effect on the market.

From observations taken near London during the last forty-two years, the average day temperature of the week is 47.9°; and its night temperature 38.7°. The greatest heat was 60°, on the 28th, 1828; and the lowest cold 9°, on the 25th, 1858. The greatest fall of rain was 1.21 inch.

THE PROPER SETTING OF A SADDLE BOILER.

THERE has been so much said lately on the different forms of boilers and methods of heating, nearly every maker of boilers having invented or patented new forms—each of which, if we believe the advertisements, is superior to any other, and more economical in point of fuel—that I feel it is rather bold of me to venture to add anything upon so well-worn a subject. It seems to me, however, that nearly every boiler-maker, in endeavouring to outvie his rivals in the trade in the invention of new forms, is making the forms so complex as to add materially to the difficulty of keeping boilers in working order, and from the inequality of expansion and contraction, adding a great element of weakness. In endeavouring, too, to make all the use they can of the vertical action of heat, they are forgetting one of the primary laws of the radiation of heat—"That heat radiates equally in every direction;" or, I might express it in another way, that the secondary law of heat, "That heated air and the products of combustion rise," seems to swallow up the first or more important law, that heat radiates equally in every direction in right lines, and varies in intensity according to the square of the distance from the source of heat. I speak of this as the primary and most important law, because it is owing to this law of the propagation of heat through a transparent medium like the atmosphere that we are indebted for the heat of the sun. This transmission of heat through transparent media occurs with the same velocity as light itself.

Why I am inclined to think that this, the primary law of heat, is much neglected, or rather set aside, is that, in talking over the matter with many gardeners, I have found nearly every one thinks that the heated products of combustion brought over the top of a boiler only heat the brickwork above, and are of little benefit to the boiler itself. Now I maintain, on the contrary, if an ordinary saddle boiler is properly set with brickwork 3 inches from the side, and arched over the top, so that the heat from the fire shall traverse all round and over the top of the boiler, in the same way as ovens in the present close kitchen ranges are heated, that the heat given off to the boiler by the flue is greater than the heat from the fire on the inner surface. I will take first the case of an ordinary saddle boiler, we will say 2 feet long, 22 inches wide exterior measure, and 20 inches high—to take a rough measure in square inches, the interior surface will be about 930 square inches, the exterior about 1250 square inches, the whole of which exterior surface may be heated from the flue. Taking into consideration that every time the fire is mended, the coal, till it is thoroughly ignited, gives no heat near the furnace door, and that owing to the laws of heat the draught from the chimney carries the heat away directly to the farther end of the boiler, it will be seen that only one-half of the interior of the boiler receives the full benefit of the fire, while the whole of the exterior of the boiler is heated; and it seems to me absurd to say that this contracted body of heated air in rapid motion should be hotter on one side than the other—*i. e.*, that it should heat the brickwork above, but not heat the boiler below.

Another objection which has been raised is, that this heat applied to the top of the boiler does no good, because as heated water rises the water at the top is hotter than the water at the bottom of the boiler, and that we ought to heat the water where it is coldest. This, I need hardly say, is entirely an imaginary disadvantage. The whole of the proper working of heated water depends upon the circulation of water in the pipes, from the law of heated water being lighter than cold water, and the superheating helps to increase this circulation. It may not be generally known that the rate of expansion of water increases very materially as it approaches boiling-point: thus, between 68° and 176°, the volume of water increases $\frac{36}{1000}$: between 176° and 212° it increases $\frac{16}{1000}$; or in other words, 1000 parts of water at 212 become 986 at 176° Fah., and 960 at 68° Fah. It is very true, again, that in a large, long horizontal flue the upper part is hotter than the bottom, but in this case the products of combustion are always seeking to rise, and the hottest and lightest air beats against the surface of the flue; but what is an argument in a long horizontal flue, is no argument in the confined and contracted flue round a saddle boiler. Any mason, too, who is familiar with setting sheet-iron ovens, knows that an oven is as much heated from the top as it is from the bottom.

There are several modifications of the old saddle boiler, which, no doubt, when properly set are superior to it; but, then, at the same time, they are more expensive. The terminal saddle and Ormson's concentric are both useful modifications. About two months ago (September 16th), I was over at Mr. Pearson's, of Chilwell, and saw Foster's boiler, which is also an improvement on the old saddle, and seemed to be doing its work well, though there was a large "hatful" of coals on when I saw it, or at all events the man whose head would suit the hat ought to have a good deal of brains; and with due deference to Mr. Pearson, I do not think he has done the boiler justice with the way he has set it, and except that he utilises the heat in his flue by making it pass through the whole length of a double span vinery, I should have said that much heat from the fire is wasted, and a great deal of heat from the boiler itself goes to heat the brickwork in which it is set. I also do not like the exterior elbows and pipes which connect the different parts of the boiler together, still I think it is one of the best modifications of the saddle I have seen.

From boilers I am naturally led to the position of pipes, and also to the position of boilers in regard to the pipes. A very great mistake I often see is that the pipes in many vineries are laid on the ground, or so near the ground that nearly half of the heat from radiation is lost, and only goes to warm the surface of the adjoining ground. Pipes ought to be placed with as free a circulation of air round them as possible, and in plant houses there is no better place than under the stages, allowing the air from the

outside to play directly against the pipes before entering the house—there are so many who cannot distinguish between ventilation, or the proper circulation of air, and draughts, and will open lights during cold easterly or northerly winds with hot sun, so as to let the air beat directly on the leaves of the plants. I need hardly say that no ventilation of houses is perfect which does not allow of a thorough change of air in a house without direct draughts.

Again, with regard to the position of boilers. One often sees boilers placed 10 or 12 feet below the level of the floor of the houses to be heated, as if this were necessary for the proper circulation of the water, and yet the same persons who go to this expense in excavating for the boiler house will not hesitate to bend the flow pipes down to go under a path, or twist them about in any way to suit their convenience, and will run hundreds of feet of piping on a dead level. Other persons, again, feed the boiler from a cistern placed several feet higher than the highest flow pipe, on the score of the pressure assisting the flow; forgetting that when the equilibrium is once established, or, in other words, that as soon as water has found its own level, this additional pressure is a positive injury instead of good, as it tries all the joints of the pipes. Again, we see these feeding cisterns placed in all manner of positions, some at the top of the furthest flow, others near the boiler, and so on, without any rule. I have even seen the supply pipe at the first bend which rises from the boiler top. Now, undoubtedly the best place for the supply pipe is the bottom of the boiler, and, if possible, it should not be connected with the pipes, but with the boiler itself. The feed pipe, too, should be one of large diameter, as the pressure on the boiler is inversely proportionate to the square of the radius or diameter of the pipe, so that the smaller the pipe the greater the pressure: and if the supply pipe is of good size, and is connected directly with the boiler, it acts as a great safety-valve, and takes the additional pressure away from the pipes which the heating of the water gives. Where it is practicable, the supply cistern ought itself to be fed from another cistern by means of a tap regulated by a ball-cock, so as to keep it always at one uniform height and to save the trouble of constant attendance; and the height of the water ought not to be more than a few inches above the level of the highest point of the flow pipe. One precaution in fixing the pipes can hardly be sufficiently attended to, and it is, wherever possible, to make the flow pipe gradually rise from the boiler to the farthest point, and to regulate the return pipe in the same manner. I have a small saddle boiler which heats a small plant house, a vinery, a stove, and two propagating pits, and the water can be made to boil in three-quarters of an hour; I attribute its efficiency entirely to the proper attention to the position of the pipes. The vinery and stove are both double-span, and contain more than 1000 feet of radiating surface of glass, which gives the boiler much work to do. The top of the boiler is not more than 4 feet below the highest point of the flow pipe.

From these remarks it will be seen I agree with the advice so often given to correspondents in your pages, that the best boiler for all practical purposes for small houses, and the cheapest, is a good saddle boiler, if it is properly set. The heat given to the brickwork round the boiler is by no means wasted, as it helps to keep up the heat of the boiler at night long after the fire is out. I agree, too, with those who condemn nearly all forms of tubular boilers, except those that have water jackets round them, and I feel convinced that no boiler is of much use where the flues require constant cleaning-out, or where the boiler is so set that it is not possible to clean them properly.

I believe Foster's boiler with a little alteration will be one of the best; but I still think, though I have not seen the conservative boiler, that for heating large quantities of piping an improved form of boiler has yet to be made; but for anything under 1000 feet a common saddle boiler will answer as well or better than almost any other, and the complex forms of tubular boilers, made on the idea of economising vertical heat only, are a step in the wrong direction.—C. P. Peach, *The Vicarage, Appleton-le-Street, Malton.*

Wellingtonia gigantea.—I forward you particulars of my best three Wellingtonias. No. 1, planted April, 1856, height, 30 feet 4 inches; circumference of branches, 54 feet 6 inches; girth of stem, 8 feet 6 inches. No. 2, planted 1857, height, 24 feet 3 inches; circumference of branches, 45 feet; girth of stem, 4 feet 10 inches. No. 3, planted 1859, height, 22 feet 6 inches; circumference of branches, 42 feet 6 inches; girth of stem, 4 feet 7 inches. All three are perfectly healthy, and have in no way suffered from cold or wind to which they are all exposed, especially No. 1, which is planted in the open park without any shelter.—J. Ridoway, *Fairlawn, Tonbridge.*

FRUIT-GROWING IN FRANCE AND ENGLAND.—No. 1.

When, some time since, I ventured to enter upon a few observations on the vegetable culture of France and England, or rather that carried on in the neighbourhood of Paris and London, I was not a little doubtful as to their reception. Statements had been very confidently put forward, and resting on apparently strong grounds, that we were lamentably behindhand, that we did not make so much out of our ground as our neighbours, and that we were continually importing from them what we ought to grow ourselves. Now, as I did not at all agree with these conclusions, I felt considerable diffidence as to the manner in which my opinions might be received; I was, therefore, very glad to receive from so many quarters approval of my statements, from persons who were thoroughly capable of forming a sound and unbiassed opinion, and this led me to desire to carry my observations a little further, and investigate the equally debated matter of fruit culture. When, therefore, I was about to pay a short visit to Paris in the past summer, I was requested by the Editors to examine the fruit culture in the neighbourhood of that city, and the results of that examination will be given in this and some following papers.

The plan that I adopted was this: I first of all made the acquaintance of M. Jamin, the eminent cultivator of Bourg-la-Reine, near Paris. I may, perhaps, best designate him as the "Rivers" of France; not with so lengthened a personal acquaintance as our veteran pomologist, but succeeding to a very extensive business, which had been founded and greatly increased by his father, one is able to see at his establishment examples in large numbers of the various systems of training adopted throughout France. Under his guidance I visited the garden of M. Charden at Chatillon, a most ardent amateur in Pear and Apple culture. I afterwards visited the garden of M. Nalet, of Brunoy, who likewise carries out the same culture to a very large extent. For Peach culture I went to the far-famed Montreuil, visited the garden of M. Lepère, and others; while on the general subject of supply I addressed myself, through the kindness of Mr. Solomon, of Covent Garden, to M. ——, Rue du Marché St. Honoré. So far, then, as to the French metropolis and its neighbourhood. In England I have availed myself of the kindness of Mr. Rivers, and visited and examined his world-renowned establishment; I also visited the extensive fruit gardens of Mr. Francis Dancer, at Chiswick; the gardens of the Royal Horticultural Society; the grounds of Mr. Myatt, at Deptford, and various private establishments where fruit-growing is carried on. It will, then, I trust, be conceded that if I fail in giving an adequate idea of the subject I have undertaken to write about, it is not because I have not gone to proper sources of information, or been chary about time or trouble; and if my conclusions be combated, I hope it will not be charged on me that I have drawn them in ignorance, or that because I may refer to what others may have said that I have copied from them, for this most amusing charge was, I understand, made in reference to my papers on vegetable culture. I can safely say that whether they be good or bad, the thoughts are my own, and that I have spared no trouble to arrive at correct information. How difficult this is may be inferred from the following simple fact:—Many persons have seen and wondered at the enormous Belle Angevine Pears, exhibited by Mr. Lewis Solomon, and marked eighteen guineas a-dozen. The ordinary idea is that they are grown in Algiers; but on inquiring at Covent Garden I was told, "Oh! no, they come from the south of France." They evidently do, because of their name. Well, when I was going over one of the fruit gardens near Paris, I was told they were grown at Belleville, in its neighbourhood; but lastly, when talking over various fruit matters with the first fruit merchant in Paris, and the correspondent through whom they were forwarded to London, I was assured, "Oh! no, they are all wrong; they are grown in Normandy." Like Sir Walter Raleigh, one might say, What folly to write anything when a simple fact is so difficult to verify.

What fruits, then, did it become me to inquire about? Certainly not forced fruits. On this point the French gardeners

are lamentably behindhand. Nowhere, except perhaps in a few places, such as the late Baron James Rothschild's, whose intercourse with England has led to the following of English practices, is the forcing of fruit carried out to any degree of perfection. Those grand private establishments where the owner prides himself on his Peaches, or his Pines, or his Grapes, are almost unknown in France, and Mr. Meredith and others have shown the foreigner that he cannot for one moment compete with the English grower. I went to see Fromert's, at Montrouge, but was struck with the comparative insignificance of the forcing, although he is distinguished as one of the chief "*primeurs*" in the neighbourhood of Paris. Who that visited the fruit exhibition of the International at Paris, but must have been struck with the poor display of Grapes that France could produce; while those grown on the English system by Mr. Knight were considered as marvels of cultivation. The out-door culture of Grapes is so small a matter in England, and so very uncertain in its results, that I do not see that any practical good could result from giving any detailed account of their cultivation in the neighbourhood of Paris. The same may be said of Figs. We are not, as a rule, "*Becceficos*," and no one would, as a matter of profit, enter on their cultivation. In Strawberries, I think, we entirely maintain our supremacy—in fact, it has only been of late years that any good-sized Strawberries were to be seen in the markets of Paris. The "*fraises de quartre saisons*," or Alpines, were the only Strawberries known; and even now the Alice Maudes and Victorias—in fact, all large Strawberries, are known in the halles as "*fraises anglaises*," while I have never seen anything like the British Queens and Sir Charles Napiers which one sees in London. There is no such cultivation of this delicious fruit as at Mr. Smith's, at Twickenham, or as there used to be at Mr. Myatt's, at Deptford. While I say this, I think we do not sufficiently value the little Alpines, of which there are some good new varieties, for often one can gather a dish of Strawberries from them when all other kinds are over. One has often been asked how it is that from April to October these little Strawberries are to be seen in Paris. The secret is simply that the earlier ones are produced at Montauban and other places in the south, then the centre of France supplies the markets, and afterwards the neighbourhood of Paris. This is one of the advantages that France possesses in having a territory that runs so far south, while its capital is in its more northern part.

It comes then, in fact, to this, that there are but three or four fruits about which anything can be said on looking at the respective fruit culture of Paris and London—the Apple, the Peach, and the Pear, and it is to these I shall confine my observations. There are one or two points which I should, however, like to say something about before I enter into this—namely, the climate, as affecting fruit culture, and the supposed greater love for and appreciation of fruit manifested in France. Neither of these questions must be lost sight of in considering this matter, as I believe the wrong conclusions which have been drawn arise from the unsoundness of the premises laid down.—D., *Deal*.

NATIONAL PROMOTION OF HORTICULTURE.

In the interest of horticulture, of which I am an earnest supporter, I offer the following remarks, hoping that wherein I fail, others may supply the deficiency. If I do nothing else but raise a discussion which may lead to future advantages to my favourite pursuit, I shall in myself be satisfied. If a more worthy or better-informed brother of the spade will come forward and carry out more fully the ideas here embodied, willingly will I give up my share in the proceeding, and work as a labourer where I would rather lead. I seek only the future welfare of horticulture and gardeners, and the benefit of the nation at large, at least as regards expense. At the present time we have many public parks and garden establishments kept up at great cost. I hail, indeed, with delight, as an ardent lover of the science, the great progress we have made in the last few years; but could not this progress be maintained at smaller cost, and with equal efficiency? I am led to these thoughts especially, from the debates on the items of the budget last session relating to the parks, &c., neither can I dismiss from my mind the fear that the funds hitherto granted may hereafter be refused to them.

Our parks and gardens have now either separate houses and establishments, or else are furnished at great cost by my friends (and I may truly call them so), the nurserymen. Could we not take a lesson from our neighbours the French, and have like them a Jardin Fleuriste to supply this want?

The next question is, Where shall we do this? I unhesitatingly reply, Kew. Already Kew is a great national institution, it is already public property, already maintained by an efficient staff, in a healthy spot, away from the impurities of London smoke, within easy distance of the London parks. Let it act as a threefold establishment—first, as a museum of plants; second, as a public rearing ground for plants for public works; third, as a college of instruction for young gardeners. Let us take these points separately.

First, as a museum. Let it be put on the footing of the British Museum; there everybody who writes a work deposits a copy. Let the same be done by those who raise or import new plants. Let a specimen be sent to Kew. Let the plants be tried for three or four, or more, years; should they then prove inferior, or should superior varieties be introduced, let them be discarded. Moreover, let a quarterly journal, illustrated by the best artists, and collections of all plants named in the letter-press, be published every quarter. On the subject of the form of the journal I will write further another time, should the idea receive public support. I have already broached the subject to many horticultural writers, but found from them that they demurred at the expense, and that the plan could not be remunerative; this would certainly apply to private individuals, or to a company, but not to a public institution.

Second, As a public rearing ground. A portion of the park at Kew could be devoted to this purpose, and I think if we copy our neighbours in France, the carriage of plants from thence to the parks need not cause us to fear for the safety of plants; so that being dismissed from our minds, we have only to look at the relative expense. I maintain one vast establishment would be kept up more easily than many scattered in the different parks. The present system need not be greatly changed, the Commissioners of Parks, Woods, and Forests, &c., would still be responsible. Under them the present heads and directors would still take charge of the various departments, and in addition be available as instructors and professors of the gardeners' training establishment, or, if you prefer it, college at Kew.

Dr. Hooker, the learned botanist and Director, might act as head, and assisted by the Regius Professors of Botany at Oxford and Cambridge, instruct gardeners in botany; the other Curators, such as Mr. Smith, at Kew; Mr. Gibson, of Battersea Park; and their worthy collaborateurs, could each lecture on the different branches of horticulture, one say take fruit, another vegetable, another sub-tropical, another stove, culture, and so on. Besides this, amateurs, gardeners, nurserymen, and other competent horticulturists, could from time to time be added as lecturers. These combined would also form the council to decide on plants to be retained or discarded.

I appeal with confidence to all classes. First, to nurserymen. The fact of sending specimens to the museum would no more injure your trade than the British Museum does writers and publishers; it would, in fact, prove your copyright to the various plants, and not being a place for sale, but only a public institution, could not affect your trade. Moreover, from maintaining only the best qualities of plants, you could clear your catalogues of many that you yourselves consider worthless varieties, and enable you to devote more time and space to the cultivation of the superior.

I appeal to the country at large, and our legislators in particular, could not efficiency be maintained by this plan at less cost? We should have, moreover, a public institution and monument of skill such as no other country can show. Our gardens and parks would be open to all as they are now, to rich and poor alike. Gardeners could gain instruction. Examinations could be held in connection with the teaching staff, and men sent out into the world capable of undertaking any branch of their profession.

I offer these few incoherent remarks, as I believe and hope, for the benefit of our art; let abler hands now lay aside the spade, and take up the pen in the cause.

Before concluding, I find I have omitted referring to the journals and societies that might consider their interests affected. First, the societies would still hold their shows, and give prizes for good productions, totally unaffected by my proposal if carried out, inasmuch as no show and no prize would be given at Kew more than there is now. The journals would be unable to give the information that would come from this establishment, and would still be as eagerly bought and read as

now. — A Wigtonshire Laird, and an Old Friend of the Journal of Horticulture.

[The scheme shadowed forth in this communication is a good one, but some of the details and the mode of carrying them out are open to grave objections. The portion of the scheme which we consider unexceptionable, is a great central school of horticulture, where lectures would be delivered on the theory and practice of horticulture, botany, and other natural sciences bearing upon horticulture, and this we hope some day to see realised; but before anything of this kind can be carried out perfectly, we must set about initiating a system of instruction in our primary schools, which shall prepare the masses of the population to benefit by that which may be obtained in a great central school. In Germany, Switzerland, and France, this is already done; but in our "land of liberty," everybody talks and does as he likes, without regarding his neighbour's or the national need. There is so much talk, and so little result.— Eds.]

GLAMIS CASTLE, FORFARSHIRE.

The Seat of the Earl of Strathmore.

Until the holding of the Great International Horticultural Exhibition in Edinburgh, in September last, how few amongst the thousands of the readers of this Journal knew anything of Glamis and its magnificent gardens! Historically acquainted we may have been with the name, as one of the most ancient castles in Scotland, as well as with that of its noble owners, the Earls of Strathmore, whose names are intimately associated with their country's history. Glamis, however, and its noble owner, are new additions to horticulture; but young as they may be, they have already attained a position high and honourable in the gardening world. Few finer kitchen gardens, or better examples of Grape cultivation, have we to see than at Glamis, and no more generous and ardent patrons of horticulture have we to admire and honour than the noble and ancient house of Strathmore. It is a pleasant duty, then, to tell our readers of this new accession, and to make them acquainted with what has been done in this northern situation during the past four years, and with what is now to be seen in gardening at Glamis Castle.

Travellers by the Caledonian Railway between Perth and Aberdeen, may remember Glamis station, twenty-four miles north of the "Fair City," as one of a series attracting the attention of the most careless passenger by their neat and trim appearance, their pretty gardens, and brilliant display of flowers, examples which we should like to see imitated elsewhere, but which we are sorry to see are now somewhat neglected even here. A walk of a little more than half a mile will bring us to the gates of Glamis, and another of nearly a mile to the Castle itself. Here, then, is situated the subject of our notice, in one of the richest and most fertile valleys of Scotland, familiarly known as the "Howe o'Strathmore," celebrated for its high-class farming, and vieing in some places with its neighbouring district, the famous Carse o'Gowrie itself, in its Apple orchards. To the north, a few miles distant, rises the mighty chain of the Grampian mountains, thus forming a fine natural shelter from the bleakest winds. The whole district is of a finely diversified character, the surface gently undulating, well wooded, and watered with the downward mountain streams, and with a soil, pure and fresh, of a rather light and sandy nature, yet rich and easily worked. Thus there are few places to compete with Glamis in the way of natural advantages.

The Castle, which dates from A.D. 800, is a splendid example of the old Scottish baronial style, built of a reddish stone, and it is still inhabited, still the residence of the family, which very few of the ancient castles of Scotland now are. There are many much more handsome-looking new edifices to be seen, and with much greater pretensions. New buildings may, however, be seen any day, but very seldom an ancient one like this, which can compare in its interior comforts and conveniences with the best of our modern mansions. How well the art of building and architecture must have been understood in those bygone ages— ages on which we fancy we have made such vast improvements! Yet in this one art we are immeasurably inferior. A great many of the old castles in Scotland are very models of ugliness, mere piles of stone and mortar, with loopholes for windows; Glamis, however, although it is so very old, has even a modern and comfortable look about it.

Surrounding the Castle is the park, of upwards of 1000 acres, in which are some fine trees, of Ash and Oak especially; the former, near the Castle, about as fine examples as any we have ever seen, with trunks nearly 3 feet in diameter. There is not much here in the way of pleasure ground or ornamental gardening to attract notice; the gardens proper being quite a distinct establishment, about half a mile distant, on the opposite side of the river Dean, a swift mountain current dividing that portion of the policies with the Castle, park, and pinetum, from the kitchen and flower gardens, whither we shall now proceed.

The gardens at Glamis, as already stated, are entirely new. It is only about four years since the present Earl succeeded to the title and estate, and the first work entered upon was the formation of the gardens. How different this from a great majority of cases, where the gardens come last in the scale of improvements! The old garden being entirely worn out, a new site was selected, and none more favourable could have been chosen. Well sheltered by neighbouring woods, and sloping to the midday sun, on the brow and side of some ground rising somewhat above the surrounding level, the situation is all that can be desired. The work of construction and formation having been entrusted to Mr. Fowler, of Castle Kennedy, who as a gardener and cultivator has already reaped high honours, we have here a specimen of his skill in the formation of gardens, and we feel bound to admit that the task has been well and ably performed, and the kitchen gardens at Glamis can now take their place as equal to the best in Scotland.

Conspicuous as the first object in view on coming to these gardens, conspicuous also by its elegant and handsome appearance, is the gardener's house. Here it forms a pleasant feature of the place, and occupies the most prominent position, as it undeniably should do; yet in how many instances do we not find the house of the gardener hidden away in some of the back slums, as if it were an eyesore, and he and his family a sort of nuisance on the place. The gardener's house at Glamis is worthy of its tenants, and a credit to its noble owner. It is pleasant also to tell how much of this is due to the wishes of Lord Strathmore himself, who took a lively interest in the whole proceedings, but more especially in this. Thus said his Lordship one day on meeting Mr. Johnston, the very able gardener here, with the architect. "We have a very important matter to settle to-day, and that is to select a site for your house. You would, I suppose, like it close to the gardens, to be convenient; it ought also to be in a free and airy situation for the health of your family, and in a position whence you could have a good look-out." The site selected is in all respects excellent, just outside the north-west corner of the gardens. To the front there is a beautiful view outside along the western wall of the garden, with the walks leading direct to the Castle in the distance, of which a view is also obtained. On the other side the eye takes in that part of the garden between the two ranges of houses where are the Pine pits, &c., and the young gardeners' rooms, which last are not the least deserving of notice. Here pains have been taken to make them comfortable, pleasant, and commodious; sitting-rooms and bedrooms, &c., being provided for all, with every convenience that could be desired.

We shall, before entering into general details as to cultivation, &c., take a survey of the general plan and arrangements of the gardens; we think we shall be best understood thus. To begin at the north, the form being that of an oblong, we have first a splendid range of three-quarter span-roofed houses, eleven in number; those in the middle of the range, the show plant house, being much higher, wider, and altogether larger than those at the two extremities. The latter are devoted, the first four on one side to Melons, Cucumbers, and pot Vines, and the other to Figs; then on the opposite side, the first two are plant houses; then there is a propagating pit, and a Pine stove, the two centre and largest houses being for Camelliaa and greenhouse plants. This is a fine useful range, only we are inclined to object to the mixed character of the houses. Fruit houses and plant houses should, we think, be kept as separate as possible. In a small place this cannot well be done, but in a large place like Glamis no such difficulty could occur. To the front of this range there are four brick pits in two ranges of about fifty lights each, two only of which are heated; and facing us against the north wall of the kitchen garden, in one long line, are the young gardeners' rooms, seed rooms, fruit rooms, Mushroom house, tool sheds, &c., all in first-class order. We enter by a door in the centre, and to the right and to the left, broken only by the gateway in the centre, we see a magnificent line of lean-to houses extending to a length of 410 feet, in ten divisions. The centre four houses are 22 feet in width by 18 feet in height at back, the other six being 20 feet wide by

16 in height. Truly a noble range! The first houses on each side are plant stoves; the second on the left is for Muscat Grapes; the third for early Grapes; and the fourth and fifth are Peach houses. On the right, the second house is a mixed vinery; the third is for late Hamburgh Grapes; the fourth is a late vinery; and the fifth is an intermediate Peach house. This, then, is the extent of the glass structures, to which we shall again allude more fully.

To the front, then, of this last magnificent range of hothouses lies the kitchen garden, which within the walls occupies an area of about four acres, with about two acres additional outside the eastern boundary wall. The shape of the garden is that of an oblong, bounded on either side by substantial brick walls, about 10 feet in height, the northern one, as just stated, being covered with glass. Along the front of the houses is a splendid wide border for the Vines and Peaches, and from this point the ground slopes gently to the south. When standing on the centre of this top walk in front of the houses, a pretty picture is before us. Leading from the top, straight through the centre of the kitchen gardens, is a fine broad gravel path, with pretty borders of flowers on either side, planted "ribbon fashion," the pretty colour of Viola cornuta telling to much advantage, and it is seemingly a plant well suited for the place. Another walk from west to east, crossing this at right angles, is made similarly ornamental. Round the walls there are the usual borders for early vegetables, &c., and on the walls very good young examples of fruit trees, such as Pears, Apricots, Plums, Cherries, and Apples. To the training and nailing of fruit trees on walls considerably more attention is paid in most gardens in the north than in the south. The same form of training it may, however, be observed is adopted for every species of tree—viz., the fan-shaped, which, although it may be exceedingly well adapted for such as Plums and Cherries, is not at all well suited for the Pear. The vegetables in the various quarters were all in first-rate condition, with scarcely a weed to be seen. Everything here, indeed, is so neat and trim, and the work finished off in such an orderly style, that to walk in a vegetable garden like this is a pleasure.

Outside the bottom or south wall of the kitchen garden runs a parallel terrace walk, with a pretty ribbon border of flowers. Here the ground slopes considerably in its natural condition to the banks of the river, which runs along at the bottom. This sloping portion has, therefore, been converted into a number of short steep terraces or banks, with a level space about 80 feet in width at the bottom, where a very pretty geometric flower garden is laid out. We must say we are not much enraptured with the style of these terraced slopes; they serve to remind one irresistibly of earthworks or fortifications. We admit the difficulty of dealing with the ground in this case in a more tasteful manner, owing to the confined space. The central main walk leading through the kitchen garden is continued in a straight line, through these terraces and the flower garden, on a steep slope to the banks of the river, which is crossed by a pretty bridge, and beyond which is the pinetum, leading up to the front of the Castle. The pinetum, although of good extent, owing to the specimens being as yet quite young, presents no feature worthy of particular notice.

(To be continued.)

GLADIOLUSES FOR SMALL GARDENS.

I was much interested by the very sensible remarks of your correspondent who hails from Chester-le-Street on this point, and it is because of this interest that I venture to suggest to him that he might do a little better in his selection of the varieties that he intends to invest in for this season. Four of those he has named are excellent; but I would alter every one of them, and would make my six to be Adolphe Brongniart, Shakespeare, Meyerbeer, Thomas Methven, Ulysse, and Madame Furtado, and these, I think, would cost about the same as those he has mentioned. I would substitute Shakespeare for Princess Mary of Cambridge, because I believe it to be a better-constitutioned flower and a model of a spike. If, however, the exhibition he has in view be late, then I would take another white, Norma, as Shakespeare always blooms early. Milton is a very imperfect flower; the individual blooms or pips are too far apart, and it very rarely shows a full face. Meyerbeer is a splendid flower, brilliant in colour, and as a spike there is no Gladiolus to beat it. Then Ulysse is, both for colour and form, one of the very best of our more recent flowers. I venture to think that your correspondent will find this a better half-dozen than those he has selected. I do not quite agree with him as to the soil, but if he has succeeded, why then by all means let him go on with it. Such freaks as he complains of in his bulb of Stuart Low are to me utterly inexplicable; I have met with them in my own garden, and believe the best plan would be to replant the young bulbs as they come up without removing the old corm, and let them take their chance.—D., *Deal*.

GROWING CELERY IN BEDS.

I for one very willingly respond to the request of your Welsh correspondent, "W. T.," page 378, and state my experience on this, to me, very satisfactory mode of Celery-growing. Like "W. T.," I have a large family to supply from a small garden, and this is the system which enables me to meet the demand for this particular vegetable, and gives me land, which by the single-trench plan it would otherwise occupy, to produce in increased quantity supplies of other requisites.

I have frequently heard pooh-poohed by gardeners the plan of growing Celery in beds; they have tried it and failed, and without trying again have condemned it. The first time I tried it I failed, but I remembered the old saying, "that nothing beats trying but doing;" I went on again and succeeded, as I am sanguine "W. T." will do in his very next lesson.

In every case of failure which I have investigated, I have found the cause to be the same—viz., the selection of sorts not adapted to this mode of culture. "W. T." has split on the same rock. With a foot of good manure and good after-attention, half his crop is comparatively worthless. With less than half that quantity of manure, and very possibly less after-attention also, I may safely assert I have not ten heads out of a thousand but that would satisfy the most fastidious Celery connoisseur.

The Celery is grown in beds, and is the fourth consecutive crop off the same plot of ground. The variety is Turner's Incomparable (true). My beds are 4½ feet wide; they are thrown out early in spring about 9 inches deep, and 3 or 4 inches of rough leaf mould and decayed vegetable mould are then wheeled in. At the end of March, or when the weather is suitable, they are filled with bedding plants planted 4 or 5 inches apart—Calceolarias, Verbenas, and Petunias; indeed, most plants from seeds and cuttings which are required for the flower garden. These are sheltered by canvas or mats, &c., and turn out in fine condition at bedding-out time. If not required for this purpose, the beds will give a valuable crop of early Potatoes, which are worth the little protection, and are always acceptable. I do not mention this method because there is anything novel in it, but because there is something good in it. I have tried it year by year for protecting flowers and vegetables, and in the absence of more elaborate contrivances, I find it answers well, and is worthy of more general adoption.

Before planting the Celery, manure, to the depth of about 5 inches, is spread in the trenches; not rich, rank stuff, but sweet and well-decayed manure, and vegetable refuse also well decayed and friable. Rich, fresh manure grows plenty of stuff to trim off for the rubbish-heap; cool sweet manure produces the quality which is esteemed at the table. I plant a foot apart all ways, and have four rows in each bed. Copious supplies of water are given, occasionally liquid manure, about once a-fortnight, and previous to watering I give a good sprinkling of common salt sufficient to whiten the ground. This I believe to be of paramount benefit, and to this more than anything else I attribute the excellent quality of the Celery. I have never used it so freely as I have this year, and have never had so satisfactory a crop.

The Celery fly (Tephritis onopordinis), which is often so destructive, I combat with soot. As soon as I see the first blister, the plants are kept thoroughly blackened for a few days. The Celery seems to enjoy this as much as the fly detests it. It should be applied, if possible, when the dew is on the leaves. The soot is of no use as a cure when the grubs have become established; it is solely a preventive, and if not applied in time is useless except as a manure.

I do not earth-up on the little-by-little system, but permit the plants to attain their full size, or nearly so, and then make almost a finish of it at once. If I were asked why I like this plan better than gradual earthings-up, I should reply, Because I have given both plans many and fair trials, and I find the one-earth system answer far the best. This year half a dozen plants bolted soon after being planted out, and I knew the

reason; with this exception I can honestly say that I have not had one bolted head a-year for at least the last four years. I tie up every plant with a bit of rough matting some weeks before earthing-up; this being done, the work of applying the earth is quickly executed. I know some object to this separate tying, on the score of its taking up too much time; now I have often more work and less time to do it in than I like, and that is one reason why I adopt the plan. I find tying is the quickest as well as the best, computing the time by either one man alone or two jointly. The tying should be done loosely, so that the tie can be slipped upwards as the plants advance in height. Of course, the plants are kept as free from suckers as possible.

A primary cause of Celery rotting is deep planting. The only real advantage gained by planting deeply is the saving of ground between the beds or rows. The early crops may safely be planted deeper than the late ones, as they will be off before the heavy fall of winter's rain. In wet soils it is advisable to plant the crops intended to remain in the ground throughout the winter quite on the general level of the ground. This precaution, and earthing-up when the plants and soil are quite dry, will generally prevent rotting.

An error in Celery-growing common to young gardeners is often made at the very outset, in sowing the seed too thickly, and coddling-up the seedlings in pots or pans, as if they were Mustard and Cress for salading.

For the main crops the first or second week in March is early enough for sowing. A gentle bottom heat, rich light soil, and scarcely any top heat, with thin sowing, are essentials in laying a good foundation for a flourishing plantation. A few barrow-loads of leaves in a sheltered place, and a hand-light or old sash are far before sowing thickly in pots in frames, with after-moving about to harden the plants off. The bottom heat to my seedling bed is from a flue which passes from one house to another, just covered with a light sash; nothing can answer better.

Another error which I will just note, is in planting too deeply. In planting, the collar of each plant should be as much above the soil as possible, otherwise it will be almost an endless job keeping it free from suckers, which the Incomparable produces so profusely.

Such is my experience on Celery-growing. Summed up it stands thus—that the bed plan suits me better than any, and the Incomparable Dwarf White suits the bed plan better than any. It gives more heart, according to size, than any sort I am acquainted with; it will come in as early as I require it, and will continue in use as late as any other; it takes little ground and little manure; in a word, it yields a maximum amount of good quality with a minimum expenditure of power and material.—J. W.

MUSHROOM CULTURE IN AN OUT-HOUSE.

This is in reply to queries from "M. McD." In a wooden house, 12 feet long, 8 feet wide, 7 feet high at back, and 2 feet high in front, you could grow Mushrooms at any time, if you could keep them cool in summer, and warm, by covering, in winter. For ease in the management of such a house, we would have a 2-feet path down the middle, and a 3-feet-wide bed on each side, which would be best done by having two boards along the passage, say 10 inches wide. The bed next the front might be 18 inches deep next the wall, sloping to the board. That at back could be deeper next the wall, or, if you chose, you might have two beds there instead of one, placing one above the other. The first plan would be the simplest, and would cost nothing for shelves. In such a case that bed might be 2½ or 3½ feet deep at the wall, sloping to the board in front. The first question, therefore, may be considered answered.

The preparation of the material of the bed will depend on its nature. If the latter be longish litter and droppings, it will require to be fermented and so much decomposed as to build rather firmly without heating violently. If chiefly droppings, if thrown together for a few days and then built firmly together, they will not heat violently. We generally mix with such about one-fourth of fibrous dry loam, as it firms the mass and prevents violent heating, and the less the manure is exhausted the better will the Mushrooms be. We have had fine beds made by a bottom of tree leaves and litter, and 3 or 4 inches of rather fresh horse droppings on the surface, adding the latter when the heat of the former was on the wane. The great point to attend to, is not to insert the spawn until the heat has gradually come down to 80°, and is slowly declining. Then insert the pieces of spawn about 8 inches apart, and so as to be covered. Let the bed alone for a few days, but if it become much warmer take the spawn out again. If the temperature is about blood heat it will be right; if it decline rapidly ten or more degrees, add 1 inch of horse droppings and beat again. If the temperature keep at the proper degree, add from 1½ to 2 inches of good soil, beat smooth, and after this if the trial sticks seem to show the temperature of the bed is sinking, add a covering of hay or litter. From 70° to 75° or 80° is a good temperature for the bed; from 55° to 60° is a good heat for the surface of the bed to be.

As regards the time the Mushrooms will be ready for market, if all go well Mushrooms may be expected in six or more weeks from the earthing-up. If they come much earlier the bed seldom produces so long, as they have had rather more heat. In this respect, under the best treatment, Mushrooms are variable as to their yielding time. In a hurry, we have had them in a month or less. We have had fine crops that did not come under ten or eleven weeks.

This is a good time for making preparations for beds, only autumn and spring are better for drying and mixing the materials a little. If even droppings are too wet they heat violently, and thus their nourishing properties are dissipated.

Besides the covering for keeping the heat in the bed, in very severe weather you might place hot manure in the pathway, and turn it over to produce a little steam in a very cold morning.

We can say nothing decisive of the quantity you could gather from such a house. As to the time of gathering, that must be when the Mushrooms are large enough, whether wanted full grown or as buttons. A much greater number of the latter can be gathered than the former. No Mushrooms should stand after they come to their best, as a few black-gilled ones will exhaust the bed more than a number not quite full grown. The mere period of gathering, morning or evening, is of no moment, but, as a rule, the nearer to the time of cooking the better. Mushrooms standing in baskets in a market are very different from the sweet-scented, juicy Mushrooms just taken from a bed.

We warn you against being too sanguine as to the market returns, until you buy experience by practice. We have, it is true, seen splendid crops in stalls of a stable which were not wanted, and that, by receiving from us fewer details than here given, but we have known other cases in which the owners of similar places professed to follow our directions to the letter, and yet proved very unsuccessful, though the material was equally plentiful in both cases.

ROYAL HORTICULTURAL SOCIETY.

Scientific Committee, *November 16th.*—W. W. Saunders, Esq. F.R.S., in the chair.

The Rev. M. J. Berkeley exhibited some Walnuts, in which the outer rind was completely blackened and shrivelled by frost, the nut in the interior being unaffected. Mr. Glaisher remarked that during winter the temperature of the atmosphere was usually considerably warmer at a level of 20-50 feet above the surface than at a lower altitude. He expressed his opinion that the peculiar appearances presented by the Walnuts were due rather to dryness of the atmosphere than to actual frost. Professor Austed called attention to the effect of wind in blackening the leaves on one side of a tree, while on the unexposed side they retained their green colour. The Chairman stated that an illustration of this fact might recently have been seen in Somersetshire, where the trees for a distance of thirty miles or more were thus affected.

Mr. A. Murray then alluded to a peculiar beetle preying on the foliage of Orchids introduced from widely diverse countries.

Dr. Masters, on the part of the sub-committee appointed to watch the progress of the plants in the experimental ground at Chiswick, exhibited a series of diagrams showing in a graphic form the relative degrees of vigour exhibited by the plants at the various dates of observation, and the fluctuations in the intervals between them. Similar tables had been prepared showing the amount of heat and rainfall during the entire period of observation, and the fluctuations in the intervals between each separate observation. Detailed notes on the condition of the plants were also laid on the table, and will probably form portion of a full report at some future time.

The most striking results shown in the diagrams were as follows:—In almost every case the plants in the unmanured boxes were the least vigorous. The application of purely mineral manures was productive of little or no result in the case of the Grasses, but was much more effective in promoting vigour in the case of the Clovers. A striking contrast was exhibited in the case of almost all the twelve separate

kinds of plants treated with ammonia salts, or with nitrate of soda respectively. It was shown in Dr. Masters' tables that almost invariably when the plants treated with ammonia salts manifested an increased degree of vigour, those treated with nitrate of soda showed a corresponding decrease. These contrasted fluctuations occurred at a time when the weather tables showed a high rainfall and a decreased temperature. Similar antagonistic results, but manifesting themselves at a later period, when the temperature was higher and the rainfall less, prevailed to a less extent in the boxes manured with a combination of mineral manures and nitrate of soda, and of mineral manures and ammonia respectively.

Dr. Gilbert remarked that the experiments, as conducted this year, were serviceable rather as indications of what to avoid in the coming year, than for any immediate use at present. The soil made use of was too fertile, and in consequence the plants made undue growth. The contrasting conditions alluded to by Dr. Masters probably depended on variations in the relative power of diffusion of the several salts, and the range of the roots. Nitrate of soda was distributed with great rapidity. The ammonia salts were converted into nitrates before absorption by the plant, and were thus distributed at a lower depth. Dr. Voelcker corroborated Dr. Gilbert as to the necessity of caution in drawing general inferences from this season's experiments, and advised that in future the plants should be grown in pots, so as to be more under control, and less subject to disturbing influences. Mr. Glaisher alluded to the effects produced by the roots of plants in increasing the temperature of the soil, and suggested that a thermometer should be inserted into each of the seventy-two boxes. These thermometers, moreover, should be made with great care, and the mercury in all should be derived from the same source, so as to secure uniformity of expansion.

A report from Mr. Barron on various experiments that have been carried on as to grafting on various stocks, was then read. The results had been very varied, and were of a very interesting character. In those cases where failure had resulted the want of success was attributed to one or more of the following causes:—Imperfection in the mode of operating; the too advanced condition of the stocks or of the buds before the operation: the want of correspondence in point of time between the growth of stock and scion, &c.

The following communication on the culture of Aloes, forwarded by Dr. Hooker, was then read.

In the cultivation of Aloes it is as well to bear in mind that they grow equally well with or without roots. There is scarcely any perceptible difference in the time required for re-establishment, between an Aloe carefully dug out of the ground with all its roots, and a rootless branch that has been broken or chopped off; both are at times liable to damp off or decay at the root.

Aloes are found growing in all kinds of soil,—rich alluvial soil, leaf mould, red clay, yellow clay, hard limestone soil, brash soil, sandy soil—in fact, every description of soil that occurs in South Africa has its Aloe or Aloes, provided always that it is rocky; for, as far as my observation extends, they do not grow where there are no rocks, neither will they continue to thrive for any length of time if they are planted in such localities. I attribute the great mortality among garden Aloes to this fact; it is not because the soils are unsuitable, for, as I have before stated, they will grow in almost any description of soil, if it be rocky.

I would therefore advise all who wish to cultivate their plants successfully, in the first place to excavate a moderate-sized hole—say, from 1 to 2 feet in depth and breadth, according to the size of the specimen they are intending to plant; fill this hole with rocks, allowing some of them to project out of the ground (these should, if possible, be ornamental); then plant the Aloe amongst the rocks, fixing it in an upright position until it is found to stand alone; then fill up the interstices with soil—any moderately good soil will answer the purpose. Do not be too liberal in the supply of water, especially at first; if the soil is moist, the Aloe will require no water at all.

After some time has elapsed, if the plant is found to be looking red and unhealthy, its root should be examined, for it may have decayed; and if this is the case it should be taken up again, and the decayed parts carefully removed or cut away, until you arrive at the sound and healthy part of the stem. The Aloe should then be placed in the sun for several days (if the specimen is large and succulent, for several weeks) to dry and harden before it is again put into the earth. It does not follow that the plant should be altogether lost because it has decayed at the root, for Aloes may be planted again and again, "even until seventy times seven," always taking the same precautionary measures.

Moreover, it will be found that Aloes will sometimes decay at the heart, or from that portion of the stem from whence spring the young growing leaves. This may be from two causes—viz., water lodging amongst the too-crowded leaves, or the larva of some insect that feeds upon that portion of the plant. An Aloe thus affected should have the greater portion of its leaves removed, and the diseased parts cut away, and the wound carefully washed and dried, after which it will soon be found that the plant will recover, and either grow again from the centre or shoot from the side.

Aloes should not be watered often nor at stated periods, for the climate of South Africa is extremely variable, and subjected to great vicissitudes, and in their wild state they are unaccustomed to a plentiful and regular supply of water. They endure long seasons of severe drought, a burning summer sun, or a scorching north wind; and, again, at other seasons they are deluged with torrents of rain, for such is the variability of the climate they inhabit; but from the construction of their leaves and roots, there is no succulent plant better enabled to endure these great changes than the Aloe, for in rainy seasons they extend every leaf and branch with moisture, and this supply is carefully stowed away, to be absorbed by degrees, in times of drought and scarcity, according to the requirements of the plant; and from this store of moisture the whole of the blossoms and seeds are frequently supplied with nourishment, which supply is obtained from the large succulent leaves of the plant, which then become red and attenuated.

Aloes should never be pruned or trimmed in any way whatever. The old leaves which accumulate beneath the large green ones, form a protection to the young growing stem, and if left to themselves they assume an oval-shaped mass of grey and hoary-looking dried foliage, which forms an excellent contrast with the green leaves above, giving the Aloe its peculiar and picturesque appearance. Moreover, the removal of this mass of old leaves frequently results in the death of the plant, which is much to be regretted.

Many of the dwarf species of Aloes are becoming much more rare within the colony than they formerly were, for I am sorry to state that Aloes, like many other succulent plants, are fast disappearing within the boundary of the colony. The sheep and goats are doing for this country what the goats did for St. Helena, rapidly altering the nature of its flora and pasture lands, and causing many plants to disappear before their destructive ravages, for in severe winter seasons, when there is a scarcity of grass, these animals are in the habit of browsing upon succulent plants, and even the bitter leaves of the Aloes are eaten with avidity.—M. E. Barber.

The Chairman remarked that the rocky nature of the country in which Aloes grew, was serviceable in preventing excessive or long-continued moisture. He had ascertained from Mr. Cooper, that many of the Haworthias grew naturally closely environed by herbage, and that when this was eaten by the sheep, the plants became unduly exposed to the sun, and died in consequence, hence the sheep were only indirectly injurious (not directly, as Mr. Barber had stated), by removing the herbage. Mr. Saunders in practice substituted a fold of thin paper or muslin for the grass, and thus tempered the light, to the great advantage of the plants.

A report from Mr. Moore on the experiments carried out at Chiswick with various chemical manures on Variegated Zonal and other Pelargoniums, with a view to ascertain the effect of the manures on the coloration of the leaves and the production of flowers, was then read. The following is an abstract from Mr. Moore's report:—

"At the suggestion of Major Trevor Clarke some experiments were commenced in July last at Chiswick, with the view to ascertain the effects of certain chemical manures on the colouring of the leaves of Variegated Zonal Pelargoniums. A set of ordinary bedding Pelargoniums was also treated in a similar way, for the purpose of noting what would be the effect of these particular manures as regards the development of flowers. The experiments were on a limited scale, and their results have so far proved to be little more than negative—partly attributable perhaps to the late period at which they were commenced, and partly to the soil employed having been of too rich a quality. As, however, there were indications of differences observable, it is proposed to repeat the experiments under somewhat different conditions another year, in the hope of bringing these out more definitely. The varieties selected for the experiments were:—*Variegated Zonal*—Mrs. Pollock, of which there were six plots, each containing four plants. *Flowering Zonals*—Herald of Spring and Norah, of which also there were six plots, each containing three plants of the former variety, and one of the latter variety. The plots, which were prepared and planted July 1st, were each 20 inches square, cut off by sinking four slates, the soil being prepared 12 inches deep. They were treated with the same kinds of manure, and used in the same proportions as those employed in the series of experiments with grasses and other pasture plants now in progress, the manures having been kindly furnished by Mr. Lawes and Dr. Gilbert. It would appear that, in general terms, the unmanured soil, and the soils prepared respectively with a mixture of ammonia and mineral manures, and with a mixture of nitrate of soda and mineral manures, gave the best results; whilst the results in the cases of the soils prepared respectively with the mineral mixture only, and with the ammonia only, were the least encouraging; and that wherein it was treated with nitrate of soda alone gave the least development, and seemed to favour compactness of growth. It is proposed another season to extend the experiments over a larger area, adopting pot culture of the plants (grown in duplicate) as admitting of an earlier commencement being made—namely, at the period of the first spring shift, when but little development has taken place, and also as permitting of a greater variety of treatment within possible limits."

A lengthy communication on the cultivation of Tea by Mr. McPherson was laid on the table, on which the Secretary was instructed to report to a future meeting.

Dr. Masters exhibited, on the part of Mr. D. T. Fish, a sample of soil in which there was a thin layer of lime about 6 inches below the surface. This had evidently been put on as a top-dressing. Mr. Fish attributed the position of the lime beneath the surface to an annual superposition of a layer of carbonaceous matter on the surface, and to the decomposition of the roots. He advanced this view in opposition

to that of Mr. Darwin, who attributes similar effects to the agency of worms. Dr. Voelcker remarked that lime so applied was always washed down gradually in the manner described.

POMOLOGICAL GLEANINGS.

About the end of last September Messrs. Rivers sent to Covent Garden a rather considerable quantity of Reine Claude de Bavay Plums. They were large, covered with a whitish bloom, and excellent in quality. They made the high price of 24*s.* per bushel, reminding one of old times, when Green Gages made 21*s.* per bushel in some seasons. The above Plums were gathered from pyramidal trees imported from Monsieur Bavay of Vilvorde, who had the property of the sort. This variety is not likely to succeed as a standard or pyramid except in the warm counties of England.

OUT-OF-DOOR GRAPE CULTURE—WINE MANUFACTURE.

(*Continued from Vol. XVI., page* 409.)

I gave the details of wine manufacture quite sufficiently, I hope, in No. 420; still, in papers treating on out-of-door Grape culture, for me not to say a special word about making Grape wine would appear like a representation of the play of Hamlet with the Prince of Denmark nowhere.

Last year was an exceptional one for the early ripening of out-of-door Grapes. Now, on the 28th of October the ice on the pond would bear the ducks, and soon after snow was upon the ground, and a north-east wind had been blowing for I forget how long; nevertheless my Espiran Grapes against the walls of this house coloured well, were plump, and ripened, and the Royal Muscadines against the garden walls also flourished. I never gather Grapes until literally obliged, on account of the enjoyment I feel whilst viewing their bountiful clusters as they hang, richly ornamenting our ugly Oxfordshire stone. Some people, however cold the weather, will sit shivering, or wrap themselves up in blankets, rather than light a fire in the grate before Michaelmas-day; others will not dig up their Potatoes until after that period, whether it involve the rotting of the tubers in the ground or no; and a good many estimable people, to my knowledge, will insist upon cutting their out-door Grapes on the second Tuesday in October, even should they prove but half-ripe, thus entailing upon themselves extra trouble in being scarcely able to dispose of them at a gift, when, if they had left them hanging on the Vines a fortnight or three weeks longer, most probably an excellent lot of Grapes just in right order for wine-making, as well as sundry bunches fit to eat, would have rewarded them for their forethought and patience. So let those who read this take notice of what I said about the manufacture of Gooseberry and Rhubarb wine, it will serve their purpose just as well for making Grape wine, merely taking care to allow one-third of water to two-thirds of Grape juice; also, when bruising the fruit, not to pound with sufficient force to crush the pips, as they would then impart a harsh disagreeable flavour to the wine. Discard honey, for I find it gives a flavour of mead; and do not use red argol or tartaric acid.

Now, presuming my readers to be up to this point in possession of the information that they will require, I will add a digest of my proceedings when making Espiran Grape wine last year; further stating that in the other Grape wines which I made—namely, Royal Muscadine and Muscat of Alexandria, my manner of going to work was, and is to be, precisely similar.

Digest.—1868, October 8th. Gathered Espiran Grapes; weight 450 lbs.

October 9th. Picked those thoroughly ripened from the bunches into a pan by themselves, crushed them, and the saccharometer floated in the pure Grape juice at 17°. Added 4 gallons of water to the juice in the pan, and the saccharometer then floated at 10°. October 10th, saccharometer 11½°; October 11th, 13°; October 12th, 12½°; October 13th, 12°. Pressed off, and it ran 17 gallons. Put 2 gallons of water at a temperature of 80° to the strained-off skins, mixed up well, and pressed it off; the saccharometer floated in this at an indication of 8°. Put a gallon of it to the 17 above, and the saccharometer indicated rather under 12°. Then added 50 lbs. of loaf sugar to the quantity, and when the sugar was quite dissolved the saccharometer floated at 44°. Covered over the pan with an old piece of carpeting in a temperature averaging 60°.

October 14th, saccharometer 47°; October 16th, 43½°. Put into cask in the cellar. November 6th, the saccharometer at the bunghole indicated 26°; November 17th, 20°; November 30th, 19°. Racked and sulphured barrel; filled and fined immediately.

December 26th, saccharometer 18°. Plain-racked again.

1869, January 30th, saccharometer 12°; April 12th, 9°. Dissolved about 2 lbs. of loaf sugar in 2 quarts of the wine, passed it in at the bunghole of the cask, and it brought up the saccharometer's indication to 11°.

September 17th, saccharometer 10°. A bottle of this wine, as drawn from the cask, was taken to the Royal Horticultural Society's meeting at South Kensington on the 21st of September. It was reported on at page 244 of "our Journal." We are now drinking this as a dark still wine, and drawn from the barrel. I wish to keep it a year or two longer in the wood, but the demand now for my home-made wines is too constant.

Espiran Champagne.—Digest.—1868, October 9th. Picked unripe berries into a pan by themselves, crushed them in a mortar with a pestle, using a circular motion, and without bruising the pips. The saccharometer floated in the pure juice of these unripe Grapes at 15°. I added a gallon of water, and the saccharometer then floated at 9½°; October 10th, saccharometer 10½°; October 11th, 12°; October 12th, 12°; October 13th, 12°.

October 14th, saccharometer 10½°. Pressed off, ran 7½ gallons; saccharometer the same; put to the juice the gallon of the second pressing of the skins, which was to spare from the ripe Grapes, and the saccharometer floated at 10°, in the quantity of 8½ gallons. Added 20 lbs. of loaf sugar, and the saccharometer indexed 39°. Placed in the working-pan, covered over, in a temperature averaging 60°.

October 15th, saccharometer in pan 40°; October 16th, 41°; 17th, 39°. Tunned the wine.

November 6th, saccharometer 17°; racked and sulphured the barrel, returned wine into the cask immediately afterwards, and fined the liquor.

December 4th, saccharometer 13°; December 26th, 10°. Plain-racked again.

1869, January 30th, saccharometer 8°. Dissolved sufficient sugar to bring the specific gravity up to the requirements of English palate—viz., 10°. March 13th, bottled.

Midsummer, began to drink this, a fine sparkling wine. October 28th, I have just two bottles of it left! Yet I smile when I think of the change that has come over the spirit of one's wine-making. Why, I declare, I was a good ten years in living down the "pooh-poohs." I can now look around and see house after house being covered with Vines. Cool vineries are rising beyond my count and ken, and some of my neighbours are becoming wine-making mad, not allowing a Gooseberry from their bushes to make a pie! One enterprising individual is buying up all the Grapes he can hear of in the neighbourhood, and I am continually receiving fresh commissions for saccharometers!—Upwards and Onwards.

(To be continued.)

PLUMBAGO CAPENSIS.

After a long silence, caused by illness and absence abroad, I have been roused from my idleness by once more seeing my favourite *nom de plume* in the pages of The Journal of Horticulture. I was induced to read the article in which it occurred, in spite of its having for its heading the name of a plant with which I am at this moment waging a war, which I much fear will end in being a war of extermination. I can only speak of Plumbago capensis as a greenhouse plant. I have what a short time since was a magnificent specimen of it trained up a pillar in the greenhouse; in the summer its fresh green delighted my eyes, and I determined it should be a real specimen plant—but how to set about it?

I had a visit from a practical horticulturist. "Ah," said he, "you patronise this old plant? Well, don't cut it, it hates the knife; you must train its long branches in and out and up in this way," and he gave them a knowing twist. So I trained the somewhat untidy sprays, bringing the moss-like heads of coming bloom conspicuously forward (as "Sally Manchester" did with the bow of ribbon on her bonnet), to the "congregation side," the "congregation" being represented in the greenhouse by a window looking into the drawing-room. Oh, the trouble I had with those unruly branches! Now they lopped down on one side, and shot up out of sight on the other. Now they entangled themselves in chignons, and flirted out in the faces of passers-by, till blue worsted and zinc wire reduced them to something like obedience. But the battle was not yet

begun. One day an amateur gardener of some experience came to see my treasures. "So you keep this nasty thing?" said he, giving a rebellious branch a contemptuous push. "Yes," I answered, a little grufily, "it is a favourite of mine." "I hope you'll like it by-and-by," said my friend, still scornfully. "And why not?" thought I. So I kept it well trained and well syringed, and first the lower part of the blossoms appeared, and faded, too, a little more quickly than was compatible with true beauty, but I waited patiently for a perfect bloom, and after awhile the mossy buds burst into a pale heaven of blue, and for a few days I felt triumphant.

The end of October was approaching, and damp days and cold nights made fires necessary, and then my Plumbago troubles came fast and thick upon me. As mothers' hearts cling to their unruly children, so my heart clung to this rampageous (I am afraid that is not a dictionary word) plant, its colour contrasted so well with Scarlet Pelargoniums and Begonias, with the pure white of Ericas, and the clear pink of Epacrises.

But the evil day was at hand. "Look here," said a friend one morning, "this poor plant is covered with the thrips, nothing will cure it but smoke." I hastened to the back of the pillar and found the leaves spotted with a yellowish-white-looking scale, with here and there a dark buff little creature, whilst the leaves still unspotted were powdered over as with salt. I was in despair, but I ordered the Plumbago a smoke bath to be taken directly. The next day things were not improved, and Pooley's tobacco powder was suggested. I flew to the syringe, gave a copious shower of water, and then of the tobacco dust, till a fit of sneezing compelled me desist; but all to no purpose. I verily believe the tiny monsters were confirmed snuff-takers, for I found them still on the leaves, and masters of the situation. Then another amateur spoke. "You will do no good till you pick off every infected leaf." I ran for scissors and knife, and cut away without mercy, till my "specimen" plant looked the most forlorn thing in Nature; then I brought soap and water, and washed branches and leaves, and then gave another syringe; after this I took away the top soil, and added fresh, looking up in the "Cottage Gardeners' Dictionary," for the most approved mixture. Then I thought I had done all I could, and looking at the poor plant with a savage mein, I said, "and if that won't do I'll cut you down, and trust to Clematis, Tacsonia, and Passiflora;" and so I will, for I love not to see a thing of beauty disfigured.

I do not see how to make Plumbago capensis useful for out-of-doors decoration in England, for it is a late-flowering plant, and could not bear the rough winds of autumn, nor the early frosts; but I have seen it in Mentone gardens blooming amidst a very wilderness of sweets, while showers of Orange petals were falling around.

And, now, I have given a true and particular account of our greenhouse Plumbago, such as "C. A. G." has asked for. I grant all that is spoken in praise of its pure sweet colouring, but it is a plant difficult to manage, and awkward in its growth; besides, it is very seldom that a perfect bloom can be obtained from its dilatory mode of coming out, which leaves the lower blossoms discoloured and faded before the upper ones are perfected.

I am writing in Devonshire, on November 5th, and blooming in my own garden, and in the gardens around, we have Cyclamens, Roses, Verbenas, Salvia patens, Coronilla, Myrtles, Violets (Czar, Devonia, and others), Pelargoniums, Chrysanthemums, Carnations (here and there one), Fuchsias, in many varieties, and other plants. I doubt if the flora of Mentone could furnish as many specimens.—Filix-fœmina.

N.B.—I have trapped a lady-cow, and have put it on a plant of Asplenium marinum infested with mealy bug, which I intend to leave undisturbed for the little lady's winter store.

BRICK EDGINGS.

I can recommend to your correspondents an edging much cheaper and more ornamental than that formed by common bricks laid diagonally. There are manufactured at Bridgewater excellent border tiles of the same material as ordinary bricks. They are made a foot long nominally, but actually somewhat over 10 inches, about 9 inches deep, and an inch thick; in fact, of the same form as terra-cotta tiles, and having a scolloped edge. I buy them from the local tradesmen at 6*s.* per hundred in any quantity, however small; and as the tiles are forwarded to the tradesman here per rail some sixteen or twenty miles, I imagine that at a greater distance the cost would be very slightly increased.—Vicar.

FLOWERING DAHLIA IMPERIALIS IN POTS.

I have succeeded in blooming the Dahlia imperialis in pots. I have now two plants of this Dahlia in 12-inch pots in good bloom, each under 6 feet in height, with good foliage, and well studded with buds to within 2 feet of the pot. Should you think it desirable, I should have much pleasure in forwarding them to the next exhibition of the Horticultural Society.—John Sharpe, *Waltham Cross.*

[Yes, we think a specimen should be sent to the Society.—Eds.]

NOTES AND GLEANINGS.

We are informed that Lieut.-Colonel Scott, R.E., F.L.S., Hon. Secretary of the Royal Horticultural Society, offers for competition at the Society's first meeting in 1870 (January 19th), five guineas (£5 5*s.*), for an essay on the principles of floral criticism.

—— An entertainment was given by Messrs. Sutton, of Reading, according to annual custom, on the 9th inst., to their staff of assistants, numbering on this occasion nearly 100. One of the large stores was set apart for the purpose, and gaily decorated. The proceedings commenced with a dinner at six o'clock. The principals were present the whole of the evening, with members of their families. The company separated at ten o'clock highly gratified.

THE COMBINED ORCHARD HOUSE AND VINERY.

In some of the later editions of my little work, the "Orchard House," I have adverted to the possibility of cultivating Grapes in the same house with Peaches and Nectarines, recommending the Vines to be 10 feet apart, and closely pruned. I felt some caution in giving this recommendation, as I had seen so many orchard-house trees injured by Vines nearly or quite covering the roof, and in this attempt to serve two masters both crops had failed. In the spring of 1865, observing one of my span-roofed houses, 100 feet by 24, to have a bare appearance, I determined to try if Vines could be enticed so as to grow up and cover the pillars.

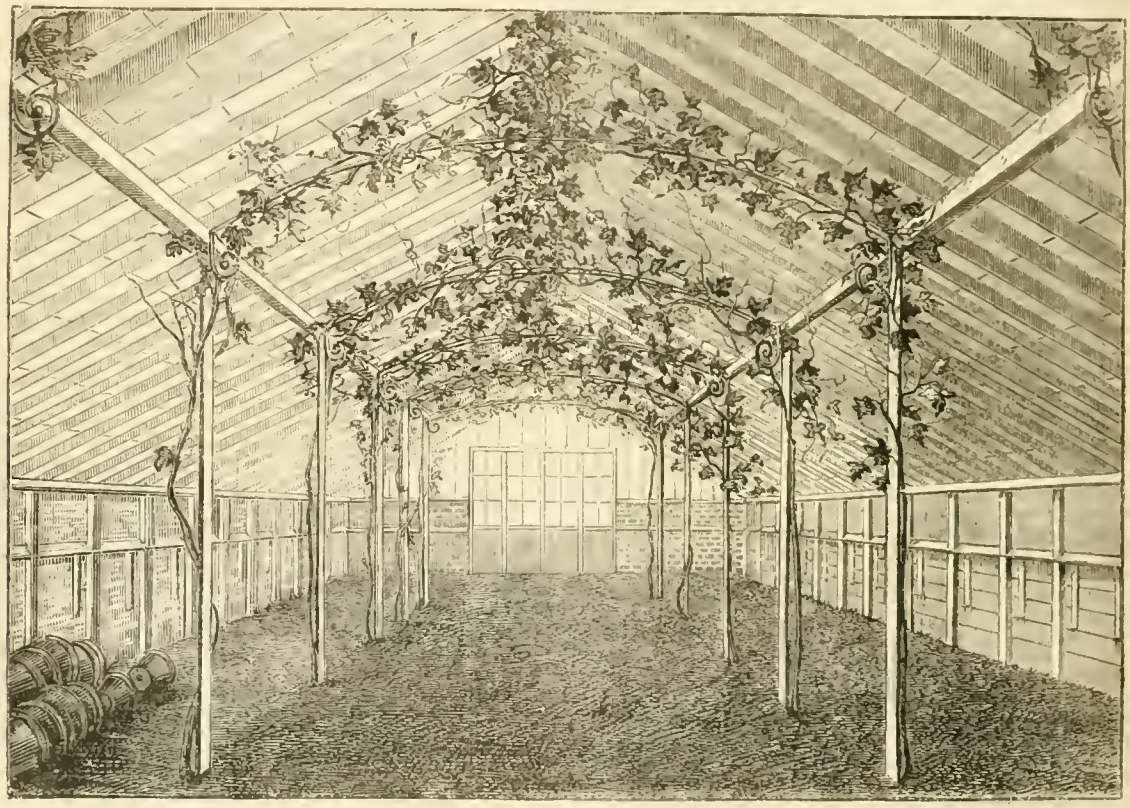
I must, however, first give a description of the house, with its good points and its appearance. It is, I repeat, 100 feet long and 24 wide; its sides are 5½ feet in height—they should be 7 or 7½ feet; its height in the centre is 12 feet—it should be 15 feet. The roof is supported inside by two rows of pillars (alias 2-inch gas-pipes), seven in each row; these are 6 feet from the sides, and are tied together, as seen in the photograph which I now send, by arches of iron rods, which keep the roof firm, and the whole building stable.

Well, it was in April, 1865, that on looking into this house and admiring the beautiful blossoms of the Peach trees, I was struck with the bare look of the "pillars" and arches, and so, as I have always thought rapidly, and acted ditto, I called one of our most active workmen and told him to take up fourteen Black Hamburgh Vines from the border close by (the border being sand, and the house standing on the boulder clay some 30 or 40 feet deep); these Vines were two years old, and had been raised from eyes and planted out. I directed my friend —for is not every workman the employer's friend?—to take a pick and make a hole about 18 inches square, and the same in depth, at the foot of each pillar; in fact, in the paths, for there are in the house a central border 6 feet wide, two paths by the pillars each 3 feet wide, and two borders next the sides each 6 feet wide. The clay was so hard—as the soil on which the house stands had not been dug for seven years—that some difficulty was experienced in making the holes. When ready, about a peck of rotten manure and loam was partially mixed with the calcareous clay, of which I enclose you a sample, and the Vines cut down to two eyes, and then planted. My single idea was that they would grow sufficiently to cover the pillars with their beautiful foliage, for Vine leaves are always "things of beauty;" but to my surprise they started at once and made shoots some 10 feet in length, and at once fulfilled their office. I remember thinking at the time that as they had eaten up their small quantity of food all at once, like a boy with his box

of sweeties, the hard clay path would stop them the following season, and that, to carry on my simile, they would be like a boy with only dry bread to eat after a pleasant gorge of sweet things. In this I was, however, agreeably disappointed, for the following season they bore numerous fine bunches of fruit, and made shoots from 15 to 20 feet long, and so they have continued to grow, covering the arches; and being carried longitudinally under the ridge and within 1 foot of the glass, they have formed, as may be seen in the engraving, a nice *tout ensemble:* in fact, I have never seen anything more beautiful in Vine culture.

The Peach and Apricot trees were removed from the house about the end of August, so that the Vines ripened their fruit in a large, warm, dry, airy space; and towards the end of last month, after having gathered a great many, we cleared the Vines of their fruit, amounting to about four bushels, every bunch perfect in bloom and flavour, and weighing from 1 lb. to 2 lbs. each. It is strange to say, that although at the crests of arches, and on the longitudinal wires, the leaves in many cases touch the glass, yet no leaves are ever scorched; not even in the hot summer of 1868 were they touched. This, I believe, is entirely owing to the glass being taken out at each end under the gables, to an extent of about 3 square feet. These apertures are open night and day, winter and summer, and in hot sunny weather the thermometer then standing at 105° among the leaves within a foot of the apex of the roof, a movement of the leaves is always perceptible, as if the comparatively cool outer air were gently but constantly pouring in. I have never witnessed this elsewhere in vineries, but I feel assured it is the perfection of Vine culture. Many good gardeners have seen my combined orchard house and vinery, and have looked in wonder at the barn-floor-like surface of my Vine borders—a misnomer.

And now comes the question, How have such means produced such results, for it seems scarcely credible that a hard unstirred floor of calcareous clay should give such healthy growth and such fruit, so fine in flavour, and so thin-skinned, as in the bunches sent. On digging some holes in the floor of the house to ascertain what the roots were doing in their apparently unfavourable habitat, they were found spreading



over the whole floor of the house a few inches under the surface, some of them having made their way to the outside under the boards forming the lower part of its sides.

The question now arises how the healthy state of the Vines has been promoted in such a soil, so different from the prepared borders so much in fashion; and first, it seems to me that, owing to the surface of the house being nearly covered with Peach trees in pots, all surface-dressed with the stimulating compost used here—saturated horse droppings and kiln dust—and the trees being watered once a-day, the roots of the Vines received a large quantity of liquid manure which would filter through the pots; and the surface being warm, moist, and shaded by the trees, would encourage the Vine roots to it, thus giving them a favourable pabulum in which they seem to luxuriate.

I must state, that in addition to constant currents of air through the apertures under the gables, the low side ventilators were open night and day in hot weather, as were the folding-doors at each end of the house.

In common with the orchard-house trees under them, the Vines were syringed, sometimes twice a-day in hot weather, till the first week in August. I trust I may be allowed to say, that Mr. Rivett, of Stratford, built this house at a cost of from £150 to £160. A house of the same dimensions as to length and width, with a height in the centre of 15 feet, and at the sides of 7 feet, can now be built for £180. It is gratifying to know, that a combination of orchard house and vinery giving so much beauty and profit, can be built at so reasonable a sum, quite equal as regards produce to those fancy orchard houses often costing £500 and upwards.—Thos. Rivers.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Asparagus haulm may now be cleared off, cleaning the ground and giving a good dressing of rotten manure; and in the case of young plants which are only very lightly covered, the manure might be mixed with a quantity of leaf soil. Apply a good solid coat 2 or 3 inches thick, if the manure and leaf soil can

be spared. The late crops of *Celery* should now be earthed-up rather closely, making the ridge as narrow at the top as can conveniently be done, and neatly finishing the sides with the back of the spade, so as to prevent as far as possible the soil about the plants becoming saturated with wet. The soil about the early crop, or that fit for use, should also be made to throw off the wet as much as possible, pressing it firmly about the tops of the plants, and making the top of the ridge narrow and smooth. Of course Celery will not be earthed-up after this season when the plants are wet, neither should it be done when the soil is wet if this can be avoided. Mixing plenty of quick-lime with the soil about the plants will be found of considerable use in preventing their rotting in winter, and it will also save them from being disfigured by slugs. *Cauliflowers* in head, if not wanted for use, may be pulled up and hung in a shed in a cool place, where they will keep good for weeks, and will be out of the way of injury from frost, unless this should be very severe. We may now expect sharp frosts at any time, and all necessary preparations should be made at once, such as having a good stock of covering for the most forward *Endive* and *Lettuces*. *Rhubarb* and *Sea-kale* may now be introduced into the Mushroom house; it is the best plan both for economy and certainty, besides doing away with a considerable amount of unpleasant labour in covering on the open ground with leaves, manure, or other materials. The following is the preparation necessary for entire success in producing these two very useful winter vegetables:—Make a sowing of Sea-kale every year on ground well trenched and manured, and, if possible, give several good soakings of manure water during the summer. At two years old these plants will be of good substance for forcing; they should be taken up in the autumn before severe weather sets in, and laid in some place where they can be easily reached when wanted. If possible force them towards spring. This prepares them for the following two or three seasons. As the roots are done with lay them in until the end of the season, then prepare ground as above, only be sure not to spare rotten dung. Cut the roots into convenient lengths for planting, and set them about 2 feet apart, using only the soundest and straightest roots, which may be planted with a common dibble a little below the surface. Thin out the crowns during summer to one or two to each stool, and, as before stated, apply manure water freely. *Rhubarb* requires similar treatment as regards sowing and the preparation of the ground, only when forcing is over it is necessary to cut the roots severely, planting only the crowns with a very small portion of the old root adhering. These may also be planted with a dibble at 3 feet apart. This, along with the free use of manure, is the preparation previous to forcing. Myatt's Victoria is the best for all purposes.

FRUIT GARDEN.

Let there be no lack of attention in the fruit-room at present, for fruit requires more care during the first few weeks after gathering than all the season afterwards. Give sufficient air to carry off damp, but nothing more, as allowing dry winds to blow over the fruit would only cause shrivelling. Strawberries for early forcing should be placed where they can be protected from drenching rains; a cold frame or pit, where either can be spared, would be the best situation for them, but the lights should not be put on save in case of rain or frost, and, indeed, the whole stock in pots for forcing would be benefited by being placed where they would be guarded from heavy rains.

FLOWER GARDEN.

Clear off at once the stems, &c., destroyed by the recent frost, and attend to the general removal of fallen leaves. In this uncertain climate it is important to have a reserve of protecting materials at hand in case of need, but it is best not to apply them till there are some indications of severe weather. If we protect carefully and the season prove mild, we may do harm. Complete all planting, and push on alterations, particularly the removal of objectionable trees, which if cut down now may be removed in frosty mornings without much injury to the turf and walks. Those who purpose making additions to their collections of Roses should do so at once, as there will be a better chance of obtaining good plants now than after the nursery has been repeatedly picked over. The present season is also very favourable for planting all but tender sorts, which had better be kept under glass until next May, but these should be procured at once, and if they can be placed in a gentle heat through the winter, they will grow freely and furnish cuttings which will root as freely as Verbenas. In preparing ground for Roses let it be trenched at least 2 feet deep, and well incorporate a very heavy dressing of manure with the soil to the full depth. It is hardly possible to make the soil too rich for any kind of Rose, particularly the autumn-blooming kinds, and 4 or 6 inches of good, rotten, farmyard dung will not be too much where the soil is naturally rather light and poor. Large-headed standards which have done blooming for the season should be cut back rather freely, to lessen the chance of their being injured by heavy gales of wind. Continue to clear the beds of their summer occupants as these become unsightly, and, after trenching or doing whatever will save time at next planting-out season, let them be furnished for the spring. Also look over the herbaceous borders and make any projected alterations there, taking up and dividing any of the coarse-growing plants that may be inclined to encroach too much upon their neighbours. The modern system of gardening is fast driving this class of plants out of cultivation, but many of them are beautiful, and if they were more largely grown our gardens would not have that naked appearance in spring which is too often seen. Sweep and roll grass frequently, and keep gravel walks hard and smooth by frequent rollings.

GREENHOUSE AND CONSERVATORY.

Take advantage of unfavourable weather for out-door work to thoroughly clean the foliage of Camellias, Orange trees, &c., for it is hardly less essential to the health of such things that their foliage be kept clean, and in a fit state to perform its functions, than that their roots be kept in a healthy, active state. It is a somewhat tedious operation to wash the leaves of a large specimen singly by hand, but, fortunately, this is seldom necessary, as most plants can be cleaned at this season when the foliage is not in a tender state, by laying them on their sides and well washing them with water at about 140° or even 160°. Throwing the water against them with considerable force will not injure the matured foliage of hardwooded plants. Any neglected specimens much infested with scale may require to be gone over with a brush for the purpose of removing the scale, as warm water will not be sufficient to clear plants of the pest. Look over the plants in the greenhouse frequently, and examine very closely those liable to suffer from mildew and damp, as Leschenaultias, Boronias, &c., for a short neglect will sometimes result in the disfigurement of a promising plant. The Boronias, Leschenaultias, Gompholobiums, &c., are very impatient of exposure to cold drying winds, and if these must be wintered in the same house with the hardier kinds of greenhouse plants, they should occupy a part of the house where they will not be exposed to cold draughts; but air must be admitted by the top sashes freely on fine days. Also exercise the greatest caution in the application of water, especially in the case of tender-rooted plants which have not well matured their season's growth, for if the balls of these be saturated, the roots will be checked and the specimens greatly injured. Therefore, never water until the ball is so dry that water cannot safely be withheld longer, and then give enough to moisten the whole of the ball, whether large or small. Keep Cinerarias and other softwooded stock clear of green fly, and endeavour to secure stocky plants by affording them sufficient pot-room, and admitting fresh air freely whenever the weather permits.—W. Keane.

DOINGS OF THE LAST WEEK.

Our work has been so much a repetition of that of previous weeks, such as hoeing, forking, wheeling, mulching fruit trees, washing pots, potting, protecting, and uncovering, that it may be as well to advert to a few matters of general interest, and which are apt to be forgotten.

Heating.—We finished last week with a few words on this subject, and that might partly be the reason why a correspondent who not only thinks himself, but has often caused us and others to think, has put to us the very searching question—"Why dilate upon furnace management, and not do more to inform us how we are to heat our little houses without sending two-thirds of the heat into the atmosphere? I was persuaded to heat my little house with hot water; the fuel wanted was to be a mere nothing, but I find it something prodigious, and notwithstanding the damper and every care, I could, I believe, boil a tea-kettle at the top of the chimney. I have been puzzling myself as to the heat so much fuel should give out, only to come to the conclusion that scarcely one-third of that heat is taken up or absorbed by the water that circulates in my pipes. I have another separate lean-to house which I wish to keep comfortable from the inroads of frost, but I dread to call in the water doctors, with the enormous fuel bill as the accompaniment.'

Now what shall we say to such an economical correspondent —and the question of economy will soon be the most prominent of all questions—but to repeat what has been said and said over again?—that there is no mode of heating houses for plants or houses for men that is not attended with waste of the heating power. The times are not yet, but we see them coming, when the heat now lost in our great plant and forcing establishments, in our villages and towns, will be made subservient to the heating of water for washing, baths, &c., or, in the shape of heated air, appropriated to help our variable climate, so that men may not only sit under, but eat the produce of their own Vines and their own Fig trees. Meanwhile we have to do with the present; and with some experience of modes of heating, and with much love for the hot-water system and the ease with which it can be applied, we have no hesitation in saying that for small houses, and where only a very moderate artificial temperature is required, the hot-water system, as regards first expense and fuel, is the most costly that could be devised. And this holds true as respects fuel, because there is likely to be nearly as much loss of heat from the chimney of a house 20 feet in length as from one that is 100 or 200 feet in length. The extra loss will ever be greatly dependant on two causes—first, carelessness after the fire is fairly going in not leaving merely a very small opening in the ashpit door and looking after the damper. Of course, in lighting up and getting the fire established, the damper must be left pretty well out, but when well established very little serves to keep up combustion. The smoke is sooner burned and the fire sooner bright if there is a small opening for air over the fuel—a very small opening does; and this principle is well attended to in several of our iron or metal stoves. There is so often apt to be a difficulty with the damper—putting it in too far or leaving it out too far —that it is a good plan to have a hole in the centre of it, say 1 inch in diameter, and then when the fire is established and the heat well up the damper may be pushed home; afterwards the small opening in the ashpit door and the opening in the centre of the damper will support a slow continuous combustion, and the heat, instead of freely passing up the chimney, will be greatly thrown back and concentrated round the boiler. As far as our own practice and observation extend, we should depend more on these matters as regards the ashpit door and the damper than upon any specified form or arrangement of the boiler, looking upon the simplest as rather the best, though not insensible to the merits of many of the new ones advertised in our pages.

The second point is keeping the boiler free from sooty incrustations. There is little chance of the part directly exposed to the fire-box becoming encrusted, but the sides and upper part are more liable, though the heat of the fire comes, but more indirectly, over them. There is no better nonconductor of heat than soot, and where only a moderate heat is required, much extra fuel is needed to heat a boiler partly covered with soot, and therefore, other things being equal, that boiler is the best which has the most convenient openings for clearing away all soot frequently with a brush and hoe. Neglecting to do this often entails additional expense for fuel. If we wished to utilise the heat that escapes from the chimney top of a boiler, though we should like to keep the boiler clean to receive all the benefit possible of the heat, provided there were room enough left for smoke, &c., we should not be particular in cleaning the sides of the chimney from soot, as the more it was soot-crusted, the less heat would be absorbed by the chimney, and the more be carried to the discharge opening. On the same principle, were we heating by a flue, the economy of heating would greatly depend on keeping the flue clean, so that the material of the flue might absorb the heat instead of so much of that heat being carried on to the chimney-top by incrustations of powdery soot. Many flues would do their work more efficiently and economically if more frequently cleaned: hence the importance of having openings for this purpose, so that the sweeping may be done without breaking or disturbing the flue.

Notwithstanding all these attentions, however, the economy of heating by hot water will ever be in direct proportion to the extent of heating; and thus, though best and cheapest where much work is to be done from one furnace, it is, as already stated, the very dearest where only one little house is to be moderately heated. We make the last remark advisedly, on the supposition that a furnace and boiler are to be worked for this individual purpose. Where a small house can be heated from a kitchen range, or from one or more gas argand burners, then the circumstances alter the case. Even when much work is done by one boiler, heat would be greatly economised if the heated air, instead of mounting the chimney, were taken some 40 feet in a flue, and that made to heat a separate house, pits, frames, or even borders for early crops.

Passing heating by gas, as having received prominent attention of late, and also because our knowledge of that mode of heating has as yet chiefly been confined to observation, we would, for the purpose, at least, of creating more discussion on the subject, state our impression, as the result of rough measurements of fuel consumed, that to secure a temperate heat in small houses—say from 12 to 35 and 40 feet in length, and from 8 to 12 in width, with an average height of 10 or 12 feet, and all lean-to's, the economy of heating will stand first for *stoves*, second for *flues*, and third for *boilers*, and that these will not stand as 1, 2, 3, but if the stove is represented by 1, the flue will be represented by 2½, and the boiler from 4 to 4½, and on to 5, if not well managed.

A few words, then, on the former two old-fashioned and simple modes of heating, but for small places the most economical as respects fuel. The cheapest-heated stoves are those that are placed in the house to be heated, and that are cleaned out, lighted, and supplied with fuel there. Had we much to do with such stoves, we would prefer brick stoves, topped with a plate of iron, and supplied with an evaporating basin on the top. They have the advantage of giving a regular genial heat; they have the disadvantage that they cannot be removed like an iron stove, and, therefore, the latter is likely to be more generally used. Unlike a flue, the chief point is to concentrate the heat chiefly in the stove. Standing mostly above the ground level, they will act best when the discharge pipe is above the feeding-door near the top of the furnace, and on the opposite side to the feeding door. This discharge pipe should never go horizontally more than from 18 to 30 inches, and then the more upright it rises the better. We have tried it repeatedly, and find it most difficult, next to impossible, to manage, when, for a particular purpose, we had the outlet pipe nearly horizontal for 8 or 10 feet. Wherever the stove is placed—near a back wall, or in the centre of the house, the discharge pipe must rise less or more perpendicularly, when at the above distance from the stove. We have a square stove sunk in an opening in the centre of a house, 75 feet by 11 feet, the discharge pipe, after the short horizontal pipe, being a common 9-foot pipe of 3 inches in diameter, and that stove has kept the house as yet a number of degrees above freezing. Coke is chiefly used, and a pole is now and then pushed up and down the pipe to dislodge any incrustations.

In all iron stoves for plant houses, we should like them to be double, or large enough to hold a fire-box from 9 to 12 inches square, quite free of the sides of the stove, or with the fire-box neatly lined with fire clay lumps. When the stove becomes very hot, approaching red, it burns the air round it, and if there are either vegetable or animal exhalations present, it tells at once on the senses, and is hurtful to the plants exposed to it. Chemists, we believe, fail to discover how the red heat affects the air, just as they frequently fail to discover what it is that brings plague and pestilence, but the effects are so apparent that no stove for plant houses or living-rooms, should be much heated if the live fuel come in direct contact with the iron sides. This, to a considerable extent, may be neutralised by an evaporating pan; and some stoves are so made, less or more on the Arnott system, that the heated air circulates all round, below as well as above the fireplace, and, therefore, if such stoves are placed in a vessel of water, there will be a constant evaporation going on, according to the heat employed. Of course, in proportion to the water evaporated, there will be near the stove a diminution of felt heat—say from one-tenth to one-fifth, but the heat thus rendered latent in evaporating moisture, will be given out again as the vapour is condensed in the coldest ends of the place to be heated. At any rate, when we have used an iron evaporating basin on the top of such a stove in the middle of the house, we have found the ends of the house more similar in temperature to the centre of the house close to the stove, than when dry heat alone was used.

Whatever the kind of stove used, it is advisable to have the top moveable, so as to clean out the stove thoroughly at times, but we prefer the feeding box to be at the side. We have a round stove fed from the top, but with an inverted funnel over part of the opening that prevents much hot air escaping when adding a fresh supply of fuel. In feeding any of these stoves in a house, it is advisable to open the ventilator in the ashpit door a few minutes previously, so as to throw a keen draught into the outlet smoke pipe, and then when opening

the feeding door there will be little of an outlet of heated air or smoke. We like our top-feeding stove very much, but we cannot set an evaporating basin on it well, and have, therefore, to neutralise the dry heat by other means. In all such stoves their good working must depend on the close-fitting of feeding and ashpit doors, and the draught and the combustion when the fire is lighted must be regulated by the smaller or larger opening in the ashpit door. A very small slit for air over the fire-box will greatly help in lessening the smoke, causing it to be consumed instead of coming like a dense cloud from the smoke tube. In many small houses a stove inside costing with all appurtenances, say, from £3 to £5, would keep a house comfortable all the winter with something like one-fourth or one-fifth of the fuel that would be required for a boiler.

We shall now make a few remarks on flues, as the next cheapest for small houses, and dispensing with all lighting, &c., inside the house. Unlike stoves, the smoke pipe or funnel of the flue is nearly or altogether horizontal, with a pipe or other chimney perpendicular at the farther end. If the flue is slightly on the rise it will draw as well; but it will draw very well on the level, with the raised chimney at the end, if *the fire-bars of the furnace be from* 24 *to* 30 *inches below* the level of the top of the flue. We have used earthenware pipes at a yard from the furnace, but we cannot say much in their favour. We have seen the stronger, harder-burnt material used for water, &c., employed with better effect. Round pipes of Portland cement, from 7 to 12 inches in diameter, make excellent flues, and if bricks are used a yard or so from the furnace, the cement stands the heat well. When pipes of any kind are used, they should go into square recesses, covered with a tile or slate, at the corners, so that all sweeping and cleaning can be done without disturbing a pipe. Flues, however, above ground are not pretty, and in small houses are apt to come in the way. Let us, therefore, once more recommend to all owners of small houses, who wish to combine comfort with economy wherever they can, Sink from 30 to 36 inches for a stokehole, to have a small flue beneath the pathway.

We had a small greenhouse unheated for years. We said to numbers of hot-water men, "Now this case of ours is one of many thousands. Can you not make it worth your while to heat such houses cheaply, and depend on the vast numbers for remuneration?" We kept for some time, but have now lost, the rough estimates. Of almost every one of these men, if we had a large job of heating, we would consider the opinion and judgment better than ours, and would be guided accordingly; but none came near what we wanted for this little house. At last, chiefly with the help of a good labourer and the assistance of a bricklayer at the furnace, we flue-heated the house at the expense of not many more shillings than it would have required pounds to heat it by hot water. The floor had been covered with 9-inch square tiles, and we made that the basis of our operations, resolving to leave the floor just as if nothing had been done. The passage was in front, so there we determined to have the flue—a flow and return. Three bricks on edge would have made the two flues. As we had bricks, we preferred brick-on-bed for strength, and though two bricks deep would have done, we used three, with their joints as small as possible. A trench was taken out of the requisite depth to suit the rest of the floor. The bottom was laid with slate, except close to the furnace, where bricks and tiles were used. Three walls of brick-on-bed for strength were used, leaving two spaces between of from 4½ to 5 inches wide for the flues. These were covered with thin tiles near the furnace, and the rest with thin slates resting on the three walls. These, covered with mortar, had the flooring tiles bedded on them, the centre of the tile of 9 inches over the centre of the flue, and resting on the wall on each side. These side walls give support on each side to the next row of tiles, which are thus left hollow for fully half their width, one side resting on the wall, and the other side on the earth, &c., of the flooring. Eighteen inches wide of surface are thus exposed to the direct heat of the small flues, and fully 6 inches on each side, making about 30 inches of heat-radiating surface. On lighting the fire, the furnace bars being pretty well sunk, the tiles begin to throw off heat in about half an hour, and very little fuel maintains the necessary warmth to keep the temperature from 40° to 45° and 50°. No smoke has troubled us, except once or twice, and a little mortar at the joints soon stopped that.

Now, much of the pleasure of having a little greenhouse close to or joined to a living-house consists first, in being able to walk into it directly from the house, and then being able to walk round it, which can always be done when the house is from 12 to more feet in width. Now, for such a house what better plan could there be, say the house measuring from 20 to 30 feet in length, than having a 5-inch flue all round beneath the pathway, a tile covering it, and the next tile on each side as above partly hollow, giving thus 5 inches of warm radiating surface, and some 12 or 14 inches not quite so warm, but considerably heated? Just think, too, of the pleasure in a frosty or dull drizzling day of having a rapid or a sauntering walk round such a house with such a dry, warm, firm path to walk upon, instead of ordinary tiles or flags! Now not half the fuel would be needed to make such a house comfortable that would be required for the best small boiler. The last two days of sharp frost that we had, a man put on rather more fire than was necessary, but it served for the two days. At the end of fifty hours the tiles were just pleasantly warm. Of course the furnace and ashpit doors were kept shut when the fire was turned out. This is another of the advantages the flue, and such a flue as this in particular, has over hot water; the heat remains so long after the fire has gone out.

We expect to be accused of retrograding instead of advancing, but we wish to be of service, not only to the possessors of small glass houses, but to the many thousands more who would have one at once but for the difficulty and the expense of heating them.—R. F.

Death of Mr. W. Perry.—At Wisemans, in the Nurseries, Sawbridgeworth, on the 20th inst., Mr. Wm. Perry, aged fifty-nine, forty-nine years of which he was the faithful assistant of the Messrs. Rivers. Mr. Perry for many years acted as judge at the metropolitan Rose Shows, and was well known and appreciated for his quiet unobtrusive manner and sound judgment. "Faithful and true to the end."

COVENT GARDEN MARKET.—November 24.

The change of wind has brought large arrivals from the Azores and Canary Islands; among other articles are the Opuntia fruit, the Banana, and some fine specimens of the Pomegranate. Home-grown produce is quite sufficient for general purposes, except Apples and Pears. French imports are moderate.

TRADE CATALOGUES RECEIVED.

F. & A. Dickson & Sons, 106, Eastgate Street, and Upton Nurseries, Chester.—*Catalogue of Forest Trees, Hardy Ornamental Trees and Plants, &c.—List of Roses, New Plants, Hardy Climbers, &c.*

James Whitehead, Croft Bank, Hollinwood, near Manchester.—*Catalogue of Carnations, Picotees, Pinks, &c.*

TO CORRESPONDENTS.

Books (*Miss Browne*).—We know of no small illustrated book on the Grasses, except Plues's "British Grasses."

PELARGONIUM PRINCE SILVERWINGS (*J. B. S.*).—You ask if the above is a Gold or Silver Tricolor; our opinion is that it belongs to the Silver *Tricolor* section, although at times, as you observe, it has the appearance of a Golden Tricolor. We should not, however, hesitate for a moment to exhibit a good plant of it, either in a collection of Silver or Golden Tricolors. It is a very pretty and pleasing variety.

HYACINTH GLASSES (*W. I. Tait*).—They are known as "Tye's Hyacinth Glasses." All seedsmen sell them.

TRETIDIUM SPECIOSA (*H. C.*).—We know of no plant so named.

CACTUSES (*D. W.*).—We consider the best work of authority on these plants is De Candolle's "Plantarum Historia Succulentarum."

FRUITERER (*Kate*).—Messrs. Webber & Co., Covent Garden Market; but as your post-mark is Bangor, you had better find a fruiterer at Chester or Liverpool.

ROSES—DATES OF INTRODUCTION (*W. H. M.*).—We cannot give you the information. About three years ago M. Margottin, Bourg-la-Reine, Paris, published a catalogue with the information, and perhaps you might obtain one by writing to him.

GESNERA LEAVES CURLED (*A Lady in Cheshire*).—The leaves may curl from the attacks of the white fly, which is very difficult to exterminate. Fumigation with tobacco being the only remedy, and that must be done moderately, otherwise the foliage of the plants will suffer. To have fine plants they should be started in good time, and grown in a brisk heat of from 60° to 65° at night, and 70 to 75 by day, with a rise from sun heat to 80° or 85°. Place them near the glass, and maintain a moist atmosphere until they are coming into flower; then keep them rather drier.

VERBENAS DUSTED WITH SOOT (*Try*).—The cutting sent appears to have been severely attacked by either red spider or thrips, if not by both, and the dusting with soot would only dry up the leaves. Soot when used fresh should be applied in moderate quantity, as it is apt to burn the young growths of plants kept in a close atmosphere, and on that account tender, especially plants which have hairy leaves—as Verbenas, Pelargoniums, &c. When plants are dusted with soot the leaves should be dry, and unless these are firm, it is better not to dust them with soot, except in moderate quantity. All you can do is to cut away the parts destroyed by the soot, and give the plants a light airy position in a cool house. They may recover.

FERNS TO ORNAMENT A SCREEN (*Mrs. J. S.*).—To dry Ferns so as to keep their colour, as they are to be put on a folding screen and varnished afterwards, we should dry them quickly by pressing them with a hot flat-iron, then paste them on the screen, and when quite dry apply the varnish.

SIZE OF THE HORSE CHESTNUT (*J. Anderson*).—To say "what is the average width of ground covered by a full-grown Horse Chestnut" is scarcely possible. The form assumed by the tree, the nature of the soil and situation, all control its outspread. They have been known to cover a circle of 60 feet in diameter, but usually we think they do not exceed 40 feet.

FLOWER SEEDS FROM CHINA (*Hong Kong*).—We do not know any of the seeds from the names they have in China. There are no doubt many plants in China which it would be desirable to have seeds of, but it would be hardly worth while to obtain seeds of those plants which have already been introduced. In sending seeds to China, those of half-hardy plants and of the more tender sorts of hardy plants, would be most suitable, selecting, of course, those not indigenous to China. In raising plants from seed from China, sow in spring in a compost of equal parts of fibrous loam and sandy peat, and cover the seeds with fine soil to a depth about equal to their diameter. Place them in a gentle heat, and keep them moist and near the glass. Continue them in heat until the plants are large enough to handle, then pot them off singly, or prick off an inch or two apart in pans, and return them to the heat, shading and keeping moist until they are re-established; then harden off, removing them to a cool airy house, and shifting as required into larger pots.

SPENT TAN (*M. C.*).—It is of little value as a manure until completely decayed; but it may be employed for covering Potatoes at planting, and spread over the ground before being dug for vegetables, it does no harm. As a top-dressing to grass we have found it most useful when applied early in March.

PRUNING PEAR TREES RECENTLY PLANTED (*A. W.*).—We would at once do whatever pruning is needed, cutting back the shoots as required. It may, however, be deferred until early in spring, the weather now being cold; but if mild, do it now. They will be all the better of a rather close pruning, especially if the plants have lost many roots in the process of transplanting. If not pruned this year, or before growth, it is likely, from the little growth that will be made, that they will not need pruning next autumn.

ESPALIER PEAR AND APPLE TREES (*Vicar*).—The branches should be 1 foot apart. Pear trees on the Pear, and Apple trees on the Crab, should be planted 20 feet apart. A distance of 15 feet is too small, unless the espaliers are more than 6 feet high. Plums do tolerably well as espaliers, but we do not recommend them. Pyramids or bushes, and standards of the commoner sorts, are preferable. Your soil will only need draining and trenching as deeply as you can without turning up any, or but little, of the clay subsoil, though it would be well to loosen the bottom of each trench. A dozen large *dessert Pears*, suitable for espaliers, are:—Jargonelle, Beurré d'Amanlis, Williams's Bon Chrétien, Beurré Hardy, Beurré Diel, Hacon's Incomparable, Marie Louise, Thompson's, Knight's Monarch, Glou Morçeau, Beurré de Rance, and Ne plus Meuris. *Dessert Apples*: Gravenstein, Hambledon Deux Ans, Cellini, Cornish Aromatic, Adams's Pearmain, Northern Spy, Lemon Pippin, Ribston Pippin, Wormsley Pippin, Red Astrachan, Blenheim Pippin, and Herefordshire Pearmain.

CHERRIES FOR STANDARDS (*Idem*).—May Duke, Knight's Early Black, Black Tartarian, Royal Duke, Late Duke, and Bigarreau Napoléon.

VINES IN AN UNHEATED VINERY (*A Young Vine-grower*).—To grow Vines in an unheated glass house, and mainly for profit, we would confine the sorts chiefly to Black Hamburgh, Royal Muscadine, and Black Champion. There would be a risk of not ripening the Muscat you name. You will do with six Vines. With a 13-feet slope of glass, we would train the Vines from near the bottom to the top, instead of longitudinally along the house. The openings over the doorways in a 26-feet length of house will do much for ventilation, but we would prefer one ventilator at the apex in the centre. We do not think that openings like a brick end will be sufficient in the front of the house, as these 20-inch-wide squares are very different from small squares. Though you give only a little air in front, you should be able to command from 4 to 6 inches all the way. For anything but Vines you would require more. You may fill your house with trees in pots before the Vines cover the roof; then there might be one or two between the Vines.

TOP-DRESSING A VINE BORDER (*E. Jones*).—Your border covered with glass need not be protected with litter, as the roots will not be liable to suffer from frost; but when the Vines are pruned the border should be lightly stirred with a fork, but not so deeply as to injure the roots, giving a top-dressing of loam three parts, half-inch bones two parts, fresh horse or sheep droppings two parts, charcoal in pieces from the size of a pea to that of a hazel nut two parts, and one part calcined oyster-shells, the whole well mixed. Cover the border about 1½ inch deep, and when dry, or sufficiently so not to cling to the feet, tread it firm. Before the Vines begin to grow, give a good watering with water 5° warmer than the temperature of the house. The loam used should be the top of a pasture taken off about 1½ inch thick, and laid in a heap for a short time so as to destroy the grass, otherwise the fresher it is the better.

MARINE AQUARIUM (*A Constant Reader*).—"Other things being equal, a marine aquarium probably will succeed just as well fifty miles inland as anywhere else. If the air be pure, the want of that slight saline impregnation, which is the principal characteristic of sea air, cannot be much felt through a medium of pure salt water. At any rate, marine aquaria do well in the suburbs of London, for a most ornamental and well-managed drawing-room aquarium was, some years ago, located on Brixton Hill. There is no necessity for changing the water at all, so long as it remains clear and of the original density. There are dealers in marine plants and animals in Covent Garden Market, and Mr. King, Great Portland Street, also supplies them.—AYRSHIRE GARDENER."

TERRACED POTS FOR GROWING LYCOPODIUMS (*M. D.*).—You have the right sort of vessel for growing pyramids of these pretty plants. The ledges should be filled with sandy peat, adding sand liberally, and then be planted with such dwarf kinds as Selaginella denticulata, S. æsia and S. densa. Give a light sprinkling with water every morning and evening, and the vessel should be kept full of water, the top being left open. These vessels when not too soft are excellent, as they keep the roots cool and moist, but when soft the water comes too plentifully through, and the ledges are only so many receptacles for water. That defect might, however, be prevented by holes through the bottom of the ledges to allow of the superabundant water passing away.

DOUBLE PYRETHRUM PROPAGATION (*Idem*.—Like the single varieties they are perennials, but in two or three years the plants, and especially those from seed, become so weak from excessive flowering as not unfrequently to die. To keep up a stock of vigorous plants of desirable kinds, the side shoots that come from near the base of the plants should be slipped off in summer, and struck in sandy soil in a shady border, planting out in autumn or early in spring. The apparently dead roots we should mulch with leaf soil, and they will probably start from the collar of the plant in spring. If, however, your soil is strong and wet the plants will hardly survive the winter, as in such soil they are little more than biennials, and the better the kind the more delicate it is. A well-drained sandy soil is most suitable for Pyrethrums.

SALTER'S VARIEGATED ARUM (*J. A.*).—It is a variety of the Arum maculatum, which always dies down in winter.

EARLY PEAS (*H. B.*).—As you have no convenience for raising the plants inside and then planting out, your only plan will be to sow a crop on the south border as soon after this answer appears as possible, the row running parallel with the wall and being 4 feet from it, so that the fruit trees on the wall may not be injured by the shade of the Peas. If you have not space on the south border, then your only alternative will be to sow in the most sunny and sheltered position you can find, preferring sandy to heavy soil. Whether in the open ground or on the south border, a crop should be sown at once, and early in February, or as soon afterwards as the weather permits, follow with another sowing of the same sort; so that if the first sowing fail the spring one will produce in due course, and if both succeed they will form a succession. Dickson's First and Best is the best early variety at present in cultivation. If your object be to obtain a dish very early, you may, at 1 foot from the south wall, sow at once a row of Tom Thumb, placing twiggy branches of Spruce among the plants when a few inches high, which will afford them a sort of protection, and you can cover them at night in severe weather with any light material, as canvas.

SULPHUR AND TURPENTINE VAPOURS (*W. A. O.*).—You will obtain sulphur vapour or fumes without placing it on a heated surface. On a surface not hotter than 160°, fumes will be emitted that are death to red spider and mildew, and not at all injurious to plants. Turpentine placed in one or two plates in a house will destroy morely bug, and every tender leaf within the house. It is a remedy worse than the disease. It ought not to be employed in houses filled with plants, though it may be used for destroying mealy bug on Vines, but then every plant must be taken out of the house.—G. A.

SHRUBS FOR A TOWN GARDEN (*C. C. E.*)—Plant Mountain Ash, Thorns, Guelder Rose, Dogwood, and Snowberry, and fill-in with Aucubas, tree Box, and Rhododendrons in front. You do not say whether the town is a manufacturing one or not; therefore, we cannot advise as we should wish; but those named withstand any amount of smoke and dust.

POLLEN OF THE MALE AUCUBAS.—"M." says that he had the whole of his male Aucubas plunged in their pots in the ground, but his gardener has taken them up and put them in a cool house, where they are all in flower, thus more than defeating his object, which was by planting in the open to retard the time of blossoming; and he wishes to know how long the pollen can be kept in a condition to fertilise the female plants when they show bloom. He has cut off many blossoms, and wishes to be informed if it is desirable for preservation to remove the petals, only preserving the stamens? We shall be obliged by information on these subjects.

CANVAS LIGHTS FOR PROTECTING BEDDING PLANTS IN SPRING (*A. B.*).—You may paint the canvas with a composition formed of linseed oil, three pints; white resin, 4 ozs.; and acetate of lead, 1 oz. The acetate of lead should be ground with a little of the oil, then add the resin and the remainder of the oil. Incorporate the whole thoroughly in an iron pot over a gentle fire, and apply the composition hot to the canvas.

This will be better than painting it with gas tar, which should be kept as far from plants as possible.

Effects of Coke Fumes (*T. G.*).—The cause of the Tacsonia shedding its leaves we suspect is to be found in the coke used in the stove. We presume you have a smoke pipe from the stove. Coke that has even a taint of sulphur or of tar will not do for stoves in the inside of houses, as the fumes will be sure to escape less or more. You will have to obtain purer coke. The drying and browning of the buds of Camellias, &c., are no doubt partly owing to the same cause, and the dry, heated atmosphere. In addition to an evaporating basin on or close to the stove, a slight syringing overhead will be useful when much stove heat is given.

Heating a Greenhouse from a Kitchen Boiler (*Thirsk*).—With an open boiler in your kitchen, you can only heat a greenhouse from it when the flow and return pipes are, the former a little below the level of the top of the boiler, and the latter when it enters a little above the bottom of the boiler. It is always unadvisable to have any part of a hot-water pipe below the level of the boiler. You may go up as much as you like, but it is contrary to nature to make hot water descend below the source whence it comes. But for the pathway you would have no difficulty, as the pipes could stand above the walls of the pit, and the return go under the pathway to the boiler, as little below the boiler level as possible. With an open boiler you cannot raise a pipe so high as to cross over the pathway. With a closed boiler, supplied from a cistern sufficiently elevated, you can do so; and if the heat in the greenhouse has to be constantly used, the simplest mode would be to take a pipe from the boiler to a cistern against the back wall, say 7 feet from the floor, 18 inches square, and a foot deep, and make that supply the boiler. A pipe from that could cross the path and join the piping on the top of the pit wall, as stated above. If the boiler had been a couple of feet or so lower in level, there would have been no difficulty, as you could have crossed under the path level, and had your piping under your front stage. Without any alteration, your cheapest and easiest plan would be to have two 3-inch pipes fastened against the back wall at the same height as the water in the boiler. The following is another hint:—Your kitchen range seems to be about the middle, and at the back of your house 20 feet in length. Would it not be possible, by removing the wall there and fixing an iron plate, or thin fire tiles, to obtain as much heat as you wanted in ordinary weather? and then a small iron stove, or two or three large bottles—say two-gallon bottles—might be filled with hot water and placed in the front of the house in very severe nights. The whole back of such a house as yours will be less or more heated by the kitchen range. Other contrivances might be resorted to. The above plan was lately tried with good results. The back of the kitchen range, nicely packed, formed part of the back of a neat little house. The proprietor did not like the look of the recess in the wall, and a slate 24 by 30 inches was fixed in the opening, with 2-inch openings at the base and at the top to keep up a circulation in this heated chamber. In summer, when no heat was wanted, two fillets of wood filled up the openings. But for the paths and the position of the boiler, hot water would be best.

Heating Two Pits from a Greenhouse Boiler (*A Market Gardener*).—You will want two rows of 4-inch pipes for bottom heat, and two for top heat in each pit, if both are to be used alike. The boiler will be able to do the work if its position be all right. See answers to other correspondents on this subject. Of course, the heating of the greenhouse and pits must be separate. When a high temperature is needed in the pits, little or no artificial heat would be required at times in the greenhouse. Piping would cost from 10*d.* to 1*s.* per foot.

Cemented Tank Leaking (*A. B.*).—If the cement tank leaks merely where the pipes enter it, it would be best to plug all up with red lead and a little tow, or lint yarn; if at other places use the same, or fill with the best cement pointed in, and if very bad wet the whole well and put a thin coating of cement all over. With pipes in the tank we would care little about having it water-tight, though it would be as well, but would cover the pipes round and above with 6 inches of open rubble instead. We think 6 feet too far for the bottom pipes to be from the glass for Cucumbers, but you can raise your plants nearer the glass, train with one stem, and bring them to a trellis 20 inches from the glass before allowing them to spread. You may thus do with from 18 to 20 inches of soil over the tank or open rubble. The heat does not act so well when it has to pass a great deal of rubble before reaching the soil.

Dividing a Pit (*A. P.*).—Your brick pit would do for the purpose proposed, and many others besides, and a light, moveable, wooden division would serve the purpose as well as a brick one, and be more handy, as you could shut off one, two, three, or more lights as you thought proper. In such a pit you could have about 30 inches of well-worked sweetened stable manure, well beaten and trampled so as not to sink much, and about 15 inches of soil, which would leave 15 inches to the glass. If at all afraid of the bed sinking, you might have some handy moveable trellis for the Cucumbers. In such a pit depending entirely on the dung at bottom, and sun heat, it would be time enough to plant out Cucumbers and Melons about the end of April or the middle of May. One light, in the mode referred to above, might at first have a deeper bed for raising the plants. When the Cucumbers were over the pits might be used for Radishes, Lettuces, Cauliflowers, or early Potatoes, to be off before wanted for the Cucumbers. If good dung linings could be applied to the outsides of the pit, then the Cucumbers could be planted earlier. If not, it will be better to have a bed in one light from 3 to 4 feet deep for raising the plants (and that can form the top of the larger bed afterwards), and plant out at the times specified.

Twelve Pansies for Exhibition (*J. Hopper.*)—*Selfs:* Eclat, Miss Muir, Queen of the Whites, and Yellow Queen. *Yellow Grounds:* Comus, Clipper, John Downie, and Prince of Wales. *White Grounds:* Alice Downie, Cupid, Lady Lucy Dundas, and Queen.

Names of Fruits (*G. B.*).—1, Nouveau Poiteau; 2, Prince Camille de Rohan; 4, Beurré Diel; 5, Vicar of Wiokfield; 6, Beurré de Jonghe; 7, Beurré Diel; 8, Winter Nelis; 9, Crasanne; 11, White Doyenné; 12, Beurré Diel. (*C. C. E.*).—The Pear marked 2000 is Delauuy. (*C. B., Bawtry*).—3, Beurré Diel; 6, Easter Beurré; 8, Napoléon; 10, Nouveau Poiteau; 11, Thompson's.

Names of Plants (*An Old Subscriber*).—Jasminum gracile, now sometimes called *J. simplicifolium*. (*Mrs. Grosvenor Hood*).—Woodsia obtusa. (*A Greenhorn*).—1, Adiantum formosum; 2, *A. affine*. (*A Lady Subscriber*).—Your Fern appears to us an extreme form of Lastrea Filix-mas, possibly that known as Lastrea elongata. (*J. T. Aldred*).—Cineraria wigandioides; Pteris flabellata. (*P. C., Derbyshire*)—1, Selaginella Kraussiana; 3, S. Martensii; 4, S. cæsia; 2, Asplenium niteus; 7, A. marinum; 5, Blechnum occidentale; 6, Hypolepis repens; 8, Pteris flabellata; 9, Cheilanthes hirta; 10, Adiantum pentadactylon. (*Maggie Willis*).—The name almost illegible on the label of your plant is Monochætum sericeum multiflorum. 1, Cincinalis flavens; 2, Gymnegramma tartarea.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending November 23rd.

Date.	Barometer.		Thermometer.				Wind.	Rain in inches.	General Remarks.

POULTRY, BEE, AND PIGEON CHRONICLE.

ORGANISATION.

Ever since the Poultry Club, for reasons which it is needless to consider here, found it necessary to commit suicide, I believe the want of *some* recognised and authoritative body, which should in some sense represent "the fancy," has been more or less felt by many of the most intelligent exhibitors and breeders. We do not want to "put down" any particular judges; we do not want something under the control of a few gentlemen who have a "view" (of all social nuisances a gentleman who has a "view" is one of the worst); but I think we do want something to which, year by year, any matters of general interest might be referred, some occasion on which subjects may be discussed, and some tribunal by which any matters on which it is desirable to know the general opinion of "the fancy," might be decided. And I have very often of late thought, that with a little ingenuity all these objects might be accomplished by the Birmingham meeting itself.

I do not wish to be misunderstood, as I should be most grievously, if I were considered as advocating a formal court of appeal to decide disputed points of judging and other similar matters. All such disputes, on the contrary, ought to be strictly prohibited. But matters of interest are continually arising, on which it is desirable people should know "what is to be the law" during the coming season—as, for instance, when hen-tailed Hamburgh cocks were discarded some years ago, or when, as frequently happens, judges find it expedient to lay more stress than formerly upon some particular point. General questions also arise—as when the arrangement of pens was so generally altered, by separating the sexes—on which the opinion of the body of exhibitors is most desirable, if it can be obtained in such a way as will carry weight.

Now that Messrs. Hewitt and Teebay are added, let us hope permanently, to the list of Birmingham Judges, it seems to me that one of the chief obstacles to the attainment of such a desirable object is removed, and that the old Birmingham meeting might with very little trouble, and without a formality which is not to be wished, be made to answer every possible end, be

greatly increased in just influence over the poultry world, and become a pleasant reunion, which should be looked back upon, and looked forward to, during the whole year.

Let us simply suppose that the annual meeting of subscribers at the "Hen and Chickens" had its basis enlarged to admit of any topic generally interesting to the fancy being introduced, either orally or by paper, not exceeding ten minutes in length, provided due and stated notice had been given; suppose all subscribers to be considered members of this—the real "poultry club" of the world, all the judges also being members *ex officio*; and that provision were made for the sense of the meeting being taken whenever desirable on any point, not a merely personal one—I cannot but think great good in many ways would result at a very small expense. And do not let the truly British institution be forgotten. Suppose an annual dinner were held, say at four o'clock in the afternoon on the day found most convenient, the tickets being only obtainable till a week beforehand at a stated sum. Would not such a gathering be a pleasant one? Would not Mr. Hewitt's good-humoured countenance appear more good-humoured still, as he looked round the room on the many whom he has served so faithfully, without charge, during so many years? Would not asperities be softened too? Surely you could hardly feel angry even with the man who had wrested from you the first prize, as you saw him sitting opposite you radiant with smiles, and, to quote Josh Billings, "With as neat a little belly on as ever you seed!" Then after dinner, not before, to business.

Such are some of the thoughts that occur to me, and which I had hoped to have had an opportunity of mentioning in person; but the early date of the Show this year will, I fear, prevent me being present except on the Saturday, and I therefore utter them through "our Journal." It is too late for this season; but still the subject may arouse more interest now than it would do at another time, and a few suggestions from others might lead to something practical for next year, if the obliging Secretary, Mr. Lythall, would be so kind as to give his valuable aid.

I wish distinctly to state that I have no crotchet of my own I particularly want to ventilate at such a gathering. But I do think when a pursuit has attained such a magnitude as the "poultry fancy," and when good fowls can find an almost certain market at the price of a cow, *some* kind of organisation is most desirable, in order to give occasional expression to its collective interests. Now, in the great Birmingham meeting it seems to me we have the material of such an organisation nearly ready to our hands, and that with a little pains the Council and Mr. Lythall might give us what is wanted, and make both a real "poultry club" and an authoritative "standard of excellence" of their great Show.—L. Wright.

CONSEQUENCES OF ASSOCIATING HENS OF DIFFERENT VARIETIES.

In some remarks of yours on the letter of your American correspondent lately, mention is made of a circumstance to which my attention has been drawn before. I had the following statement from a poultry-fancier in Hampshire, who will possibly read this, and who will, I hope, correct any mistake that I may have made. I do not feel at liberty to use his name without his consent, and as I have not his address by me I do not know where to write to him. He will probably authenticate what I say.

Some Spanish hens and Buff Cochin-China hens were kept together, both kinds being carefully bred birds of the best sorts. With them was a Spanish cock equally good. The Spanish chickens were occasionally buff in colour, or with buff feathers. It is some four or five years since the account was sent to me, and I have forgotten these particulars. I mentioned the subject several times to medical men, who gave me reasons why it was physically impossible that any influence could be conveyed by the male bird from one to the other of the kinds of hens—an idea which in the first instance suggested itself to me. There is, therefore, no way left of accounting for the matter in this case, as in that mentioned by yourself, but by the same influences which arose from the rods "pilled" by Jacob, whereby the cattle became "ringstraked, speckled, and grisled."

I regret that I have not tried the experiment of keeping breeding hens in places having stripes of colour painted on them; when I have more time to attend to poultry-keeping again I shall do so. I hope some of your correspondents will in the meantime make the attempt, or will favour us with their experiences in the matter of colour and its changes. I think it is pretty certain that white and black, and white and yellow, are interchangeable colours, whilst red remains unchanged. In evidence of this are the breeding of Pile Game, where all the black feathers of the Black Red become white, as do the golden or yellow feathers, the red feathers remaining of the same colour; and that with age Hondans seem to change the black for white feathers and the white for yellow; whilst there is a tendency also in white birds to throw a yellow tinge.

Some may say, *Cui bono?* I really cannot answer them otherwise than in this way, that there is nothing in the laws of nature which is not worthy of examination, and that the experiments of those who have the leisure to attend to very small matters have often led to the greatest and most valuable results; and this I think a sufficient answer.

I must add that an American contribution to your columns is an event much to be prized. I hope it may be repeated, and that papers from other countries, narrating experience or asking questions, may follow. It is in this way that the sum of human knowledge is made up, and knowledge tends to make men better Christians. Some may smile that poultry-keeping should be thus exalted; but granting the unimportance they would claim for it, they cannot deny that the "mickle" affects the "muckle," and that everything which is done should be done well and with intelligence. Besides which, all that tends to throw men together in fellowship—to make them better acquainted with one another, however simple it may be, is of more value than the most elaborate schemes for fencing about a national or an individual exclusiveness.—Egomet.

OUR POULTRY SHOWS.

I quite agree with "Egomet" in his remarks about "our poultry shows," and the objectionable practice of committeemen exhibiting, some hoping, no doubt, that the prizes they may win will repay them for their subscription and leave something in pocket besides. If shows are to be made a matter of profit or loss to individual managers, let these open business places and manage them as such; but I think most of us look upon poultry and other exhibitions as a means to encourage us to improve the breed of our stock, and to enable those who take an interest in this for the love of it to compete with their fellow amateurs, and to have an opportunity at these competitions to select the best stock for the improvement of the particular kind or kinds which they prefer; also to form a correct idea, from the decisions of experienced judges, of what are the most important points required, that they may endeavour to obtain these in their own breed.

There is another objection that I have not yet seen noticed, and that may not at once occur to your readers, but which I know seriously prevents the more conscientious committeemen from undertaking the arduous and unthankful office. Allowing the committee succeed in pleasing all exhibitors, and have had numerous cheering and satisfactory letters that the owners have received their stock in good condition, &c., three or four of the "pecuniarily disinterested" but hard-working and liberal committeemen, may have all their pleasure damped when they find they must each again subscribe a considerable sum in order that one of their number, equally responsible, although, perhaps, not equally hard-working nor liberal, and certainly not enjoying the other qualification, may be paid his prize money—fairly won, it may be, and probably is—to the amount of, say, £20 or £30, and also let it be the whole amount of the deficiency; in that case it places him in an unenviable position, and his partners in the unpleasant one of feeling that his profit must come out of their pockets.

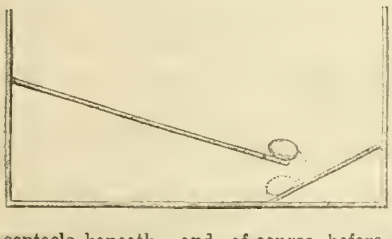
In one instance, I know, an official showed his stock, "not for competition." This is commendable, as it helps the funds in the way of entrance fees and improves the exhibition, and his birds were allowed to be the best in the show. Although a comparatively poor man in worldly goods, he generously gave his time and money, and then had to pay something like a sixth of his yearly income to help to make up the prize-winnings of his much richer fellow official, who had competed for the best prizes, and, it may be, borrowed stock from a friend to enable him to do so successfully. I may say that I am not myself one of these, neither related to nor even on friendly terms with them; but the case is a true one, and I should be glad to see the cause of it discouraged as much as possible. Claude.

Birmingham Show.—With the approach of the period for the holding of the twenty-first of these great annual meetings on

which Birmingham has abundant reason to congratulate itself, the arrangements are progressing with the prospect of a most satisfactory result. As compared with former years, the entries are far above the average, and we are informed that a considerable number of cattle have been refused. The prizes for sheep having been much increased, a grand display is anticipated, particularly from the local Shropshire breeders, whilst there is no doubt that the exhibition of pigs will maintain its character as one of the first in the kingdom. The raising of the fees on poultry has slightly diminished the numbers; but 2500 pens of nearly every known variety of fowls and Pigeons will certainly be as many as most visitors will care to inspect. The root and corn show forms a most useful and interesting feature, and will be far better than anticipated in the earlier part of the season. As regards the space appropriated to implements and miscellaneous articles, we understand that the applications for its allotment have been unprecedentedly numerous—so much so, indeed, that in nearly all cases they have had to be curtailed. Concerning the probable attendance, we have to state that the facilities afforded by the railways for the conveyance of visitors from other parts of the kingdom, by special and other trains, will be much increased by the recent opening of branch lines, and by the liberality of the concessions made by the various companies in this respect, the excursion trains being most numerous and at particularly low fares, the districts from which these run comprising the whole of Yorkshire, Lancashire, Wales, Salop, Northampton, Leicester, Derby, Cambridge, Cheshire, Hereford, Gloucester, Worcester, &c.

HENS EATING THEIR EGGS.

I HAVE been pestered with cannibal hens; but, by a contrivance of my own, I have completely put a stop to their cannibalism, without the trouble of watching or the necessity of killing the offenders. My plan consists simply in an improved nest or laying box (see accompanying section) with a false bottom, forming an inclined plane, down which the egg rolls as soon as laid, into a receptacle beneath; and, of course, before the hen can have a chance of pecking it, the egg is beyond her reach. Neither hay nor straw must be used in the nests, but if the surfaces of the inclined planes are covered with smooth matting, a piece of old carpet, or sacking, every purpose will be answered. Another advantage of this laying box, is that where several hens use the same nest, the eggs are not soiled by their dirty feet in wet weather.—TYPO, *Southport*.



ENGLISH SKY TUMBLER PIGEONS.

SOME months ago I wished to raise a new cote or loft of our old English Sky-Tumblers, and found the breed extinct, or too scattered, for selection. The little light blue, or black, and mahogany, whole colours, were my fancy. I looked your Journal over and over for weeks, and inquired far and wide without success. Lots of Short-faces (useless except as aviary pets), and clumsy cross-breeds, I found, but the tidy, tiny, English acrobat, Swallow-form, and that would fly like a Lark in the sky, was not to be found. I wanted a fresh stream of this blood, and it proved to be exhausted in the country.

Well, I procured a draft of half a dozen birds from Birmingham, warranted to fly and tumble—not Rollers that lose flight and fall—as well as the old English breed—namely, to fly high and close, and cast single rapid tumbles, almost quick as lightning, and keep up any time desired. These birds are of larger form than the little English Tumbler; blue, black, and red, with white flights, but not white tails, pearl eyes, and clean coral legs, and their aërial performances are good, though not so agile as those, I think, of the smaller English breed.

In breeding, these birds throw muffed or feather-legged offspring occasionally, indeed often, hence I infer a continental origin—German or Dutch probably; and I conclude that they are a cross between the continental and English Tumbler, and betray their foreign connection by throwing the muffed-legged young birds, breeding back frequently: some young are clean, others muffed, on the legs in the same nests.

Can you inform me and other fanciers, if a mixed English and continental breed of Tumblers is bred in Birmingham for flying, as these birds, I assume, are bred and drawn from a cote of such birds?—READER.

[Your birds have evidently a cross. Most probably they were bred from English on one side, and part Roller on the other. You need not despair of getting the old English whole colours, red and buff; the former you term, not unaptly, mahogany colour. In Birmingham you will not find them, but John Hobbs, dealer, Friar Bridge, Bath, will get them in a few weeks or months, or even days, as in the west of England—the quiet unchanging west—they are still kept, and with their tidy form, clear pearl eyes, and coral feet, without even the suspicion of a feather, are among our best Pigeons for general purposes of amusement and interest. We have seen beautiful Buff ones at Hobbs's within the last year. Black and Blue are not to be had so easily. The Birmingham Roller is the most vulgar of all Tumblers, and if it were extinct to-morrow it would be well, but, unfortunately, it suits those who only care to see the feat of turning over in the air constantly repeated, and these birds crossed with bad-bred Short-faces fill the bird shops. If our memory serve us rightly, Blue birds, such as you want, have been advertised during the last two years in this Journal.—WILTSHIRE RECTOR.]

A QUID PRO QUO.

"AN OLD COMMITTEEMAN" thinks my letter of November 11th "more amusing than instructive." I meant it to be amusing. I did not see any reason for attempting to make it instructive. The inference, however, which I wished to convey, your correspondent has correctly drawn in his own words—namely, that committeemen should not exhibit at their own show.

"AN OLD COMMITTEEMAN" thinks that I should have pointed out the way to induce committeemen "to work, without that '*quid pro quo*,' a fair chance of the prizes" at their own show. I do not see any necessity for doing so. If committeemen desire anything of the kind, then they are hirelings, with an indirect and inadequate wage. I say that, as a body, they do not require any such reward. If I am wrong, it is better that poultry exhibitions should decline, as the "OLD COMMITTEEMAN" seems disposed to think they would. Such is not likely to be the case, however, as committeemen who do exhibit in their own show are, in the average of shows, but a small minority; and I am satisfied that many of those committeemen who now exhibit under these circumstances, would withdraw from competition the moment their attention was called to the matter.—EGOMET.

THE GUINEA FOWL.

I VENTURE to call the attention of poultry lovers and fanciers to that very beautiful, useful, interesting, but very much neglected bird, the Guinea fowl.

I have looked in the list of nearly every poultry show that has appeared in "our Journal," and I have never once found any notices of it, if I remember aright. Now, why is this? In every poultry book I have seen there is, at the end of the chapter on various kinds of poultry, a notice of about a dozen lines, dry, uninteresting, and cold, declaring the bird to be wild, useless, clumsy, ugly, a bad mother, its flesh horrid, its peculiar cry worse than all. People read and believe this, and give the poor Guinea fowl no place in their pen, yard, or enclosure.

Now, I flatly contradict all this. With proper care and kindness the Guinea fowl is no wilder than the Turkey, and does not stroll away or lay in worse places than the Turkey. It is a far more loving mother, although it sits so late in the autumn that it is advisable to place its eggs under another hen. The eggs themselves are excellent though rather small, and the flesh is beautiful (I speak from personal experience), tasting very like pheasant. As for the bird's peculiar cry, persons who have lived in the country all their lives, who have been surrounded by all kinds of living creatures, and who are awakened every morning by the cackling of Geese, quacking of Ducks, crowing of cocks, clucking of hens, and chirping of chickens, will acknowledge that they could scarcely hear it, and certainly never care for it; while those other persons who are afflicted with delicate nerves had better not keep poultry.

We have kept Guinea fowls for years, and have made great

pets of them. One in particular is so extremely tame that if the henwife does not give it what it wants it "ketches" (as she expresses it), hold of her skirt, and pulls it until she yields to its wishes; it also sits on her knee at dinner, and does not scruple to help itself to any tit bit. This pet bird rejoices in the name of "Moses" although of the softer sex, and comes in and ont of the house as it pleases.

We have had very little difficulty with our Guinea fowls. They were reared so tame that they seldom laid away. The worst was the rearing; in 1866 the mortality among the chicks was great, but it was in autumn, which, as we all know, was "dark and dreary" in the extreme. If they are treated exactly as young Turkeys they will do very well, but they grow so fast that they require food every half hour.

I have now "said my say" about Guinea fowls, and I hope that some of the readers of "our Journal" may respond to this as they have done to "One of Many Witnesses."—Ida.

TURKEYS WITH SKINS TURNING YELLOW.

A lot of fine Turkeys, and seemingly in good health, have recently turned quite yellow in their skins. The food given is barleymeal and mangold wurtzel. They have run in the park, and have no doubt picked up considerable quantities of acorns, hawa from the thorn trees, and beech nuts, with which the ground has been literally strewn. They have had the same park run in previous years, which has not been followed by this unwelcome yellowness of skin.—C. L. M.

[Mangold wurtzel has the effect of rendering the fat of bullocks intensely yellow, and it is probable that it has the same influence on the fat of Turkeys. When one is killed the layer of fat beneath the skin in such case will be found to be very yellow.—Eds.]

AYR ORNITHOLOGICAL SOCIETY'S SHOW.

The eighth annual exhibition of this Society took place in the Assembly Rooms, Ayr, on the 13th inst., and was admitted by competent judges to be, as regards the number and quality of the birds, the best which has been held in Scotland, out of Glasgow, for many years. In the absence, from illness, of James Hnie, Esq., of Glasgow, his place as Judge was well supplied by Messrs. A. Cowan, G. Steele, and A. Glass, the latter of whom handsomely withdrew his birds from their pens to save all grounds for reflection. The following were the awards:—

PIGEONS.

Pouters (Young).—1, J. Sharp, Johnstone. 2, D. Munn, Kilmarnock. 3, A. Wright, Edenbank, Morningside, Edinburgh. *vhc*, J. Mair, Kilmarnock. *hc*, D. Young, Ayr. *c*, G. B. Phillips, Dalblair House.

Pouters.—1, J. Waddell, Acrehead, Dumfries. 2, J. Butler, Glasgow. 3, J. Mair. *vhc*, J. R. Adam, Ayr. *hc*, J. Scoular, Kilmarnock. *c*, J. Finlay, Lanrieston, Edinburgh.

Carriers.—1, J. Mair (Black). 2, D. Munn (Black). 3, G. Dart, Acrehead, Dumfries (Dun). *vhc*, Miss E. Beveridge, Ayr (Dun). *hc*, W. Crawford, Beith (Black).

Tumblers (Short-faced).—1 and 2, W. W. Beveridge, Ayr (Almonds and Kites). 3, J. Mair (Yellow). *vhc*, J. Sharp (Almonds). *hc*, W. W. Beveridge (Almonds). *c*, W. W Beveridge (Splashed).

Barbs.—1, W. Crawford (Yellow). 2, J. Sharp (Black). 3, Miss Beveridge (Black). *vhc* and *hc*, G. Dart (Black and Red). *c*, J. Mair (Black).

Fantails.—1 and 2, J. Sharp (White and Blue Saddles). 3, Miss Beveridge (White). *vhc*, R. Gibson, Kilmarnock (White). *hc*, W. Crawford (White). *c*, Miss Beveridge (White).

Jacobins.—1, W. McKinlay, Kilmarnock (Red). 2, J. Mair (Red). 3. Miss Beveridge (Black). *vhc*, C. Murdoch, Corton, Ayr. *hc* and *c*, Miss Beveridge (Red and Yellow).

Trumpeters.—1, D. Munn (White). 2, J. Sharp (Black Mottle). 3, M. Skinner, Edinburgh (Black). *vhc*, J. Mair (Mottle). *hc*, R. Banks, Broomberry (Black). *c*, Miss Beveridge (Black).

Turbits.—1 and 2, J. Waddell (Yellow and Black). 3, Miss Beveridge (Red). *vhc*, J. Scoular (Blue). *hc*, Miss Beveridge Yellow). *c*, J. Sharp.

Owls.—1, J. Mair (Silver). 2, Miss Beveridge (Blue). 3, J. Sharp *hc*, R. Gibson (Blue). *c*, Miss Beveridge (Blue).

Nuns.—1, W. McKinlay. 2, D. McCreath, Forehill. 3, T. Imrie, Bourtree Park. *hc*, R. Gibson.

Tumblers (Common).—1, J. Sharp (Black Mottles). 2, W. W. Beveridge (Red). 3, J. Grunton, Wallacetown (Black). *vhc*, W. Crawford (Blacks). *hc*, W. W. Beveridge (Red Mottles). *c*, J. Grunton (Yellow).

Any other Variety.—1, J. Sharp (Magpies). 2, T. Imrie (Black Priests). 3, Miss Beveridge (Magpies). *vhc*, J. R. Adam (Black Magpie). *hc*, Miss Beveridge (Dragoons). *c*, J. Grunton (Common).

Selling Class.—1, Miss Beveridge (Pouters). 2, D. McCreath (Nuns). 3 and *vhc*, Miss Beveridge (Pouters and Fantails). *hc*, W. W. Beveridge (Blue Beards). *c*, D. Munn, (Trumpeters).

CANARIES.

Yellow (Young).—*Cocks.*—1, J. E. Graham, Kilmarnock. 2 and 3, J. Conn, Annick Lodge. *Hens.*—1, R. Crawford. 2, D. Holden. 3, J. Graham.

Buff.—*Cocks.*—1, R. Crawford, Kilbirnie. 2, E. Brangan. 3, J. Graham. *Hens.*—1, R. Crawford. 2, J. Langhland. 3, W. Paterson.

Piebald (Yellow).—*Cocks.*—1, T. M'Murtrie, Riccarton Toll, Kilmarnock. 2, J. Scoular. 3, R. Stevenson, Galston. *Hens.*—1, J. Scoular. 2, A. Hamilton. 3, G. Hamilton.

Piebald (Buff).—*Cocks.*—1, J. Scoular. 2, E. Brangan. 3, G. Hamilton. *Hens.*—1, R. Stevenson. 2, M. Adam. 3, H. Calder.

Goldfinch Mule (Yellow).—*Cocks.*—1, J. R. Adams. 2, T. Murtrie.

Goldfinch Mule (Buff).—*Cocks.*—1, W. Goudie, Mainholm. 2, J. Laughland.

Parrots (Shell).—1, R. Boyd, Ayr. 2, W. Robertson, Newton.

Parrots (Any colour).—1, Capt. Kidd. 2, C. Hill.

MEMBERS' COMPETITION.

Yellow.—*Cocks.*—1, M. Adam. 2 and 3, W. Morrison. *Hens.*—1, W. Morrison. 2 and 3, J. Adams.

Buff.—*Cocks.*—1, W. Smith. 2, J. Adams. 3, M. Adam. *Hens.*—1, W. Smith. 2, W. Kerr. 3, J. Adams.

Piebald (Yellow).—*Cocks.*—1, W. Kerr. 2, W. Morrison. 3, J. Adams. *Hens.*—1, H. Calder. 2, J. Adams. 3, W. Morrison.

Piebald (Buff).—*Cocks.*—1, W. Smith. 2, J. Adams. 3, M. Adam. *Hens* —1, M. Adam. 2, W. Smith. 3, J. Adams.

Goldfinch.—1, 2, and 3, A. Hunter.

The Judges of *Canaries* were Messrs. J. McCulloch and McKenzie, of Ayr, J. Graham, Kilmarnock, and G. Haddon, Kilwinning: for *Foreign Birds*, Mr. J. Sinclair, Ayr.

THE LIVERPOOL POULTRY SHOW AND SALE

BY AUCTION AT MESSRS. LUCAS' REPOSITORY.

Few amateurs anticipated so successful a result as accompanied this spirited adventure. Messrs. Lucas offered as premiums eleven silver cups as first, and an equal number of sovereigns for second, prizes to the principal classes of poultry. These brought together a considerably better collection than is to be met with at the generality of our poultry shows. The cups were unusually good. Every cup of the eleven, otherwise altogether plain, was ornamented by a shield, on which the variety of poultry that won it was artistically depicted. These cups, it is worthy of note, were intrinsically fully worth the five guineas; they each represented a subject that might with benefit be copied by not a few of our poultry committees; 246 pens were received, and we are informed, that though the bulk were sold at most remunerative prices, the highest figure obtained for a single specimen was £12.

Dobkings.—Cup, Admiral Hornby, Prescot (Grey—sold for £5 4*s.*). 2, J. Copple, Eccleston. *hc*, W. W. Rutthidge, Shortend, Kendal (Grey and Silver-Grey); E. Leech, Rochdale; R. Smalley, Lancaster (Silver-Grey). *c*, T. Briden, Earby, Skipton.

Game.—Cup, J. Wood, Haigh, Wigan (Black-breasted Red—£6 8*s.* 6*d.*). 2, J. Fletcher, Stoneclough, (£10 10*s.*). *hc*, J. Fletcher (£8 8*s.*); T. Mason. *c*, J. Statter.

Cochins.—Cup and *hc*, Bowman & Fearon, Whitehaven (Buff and White). 2, C. Sidgwick, Ryddlesden Hall, Keighley (Buff). *c*, C. Sidgwick (Partridge); J. Clark, Thirsk, Yorkshire (Partridge).

Brahmas.—Cup and *hc*, W. Gamon, Chester (Dark—£6 12*s.* 6*d.*). 2, E. Leech. *c*, Rev. J. Chapman, Elkesley (Dark).

Spanish.—Cup, H. Beldon, Bingley (£4 17*s.* 6*d.*). 2 and *hc*, E. Comber, Myddleton Hall, Warrington (Black).

Hamburghs.—Cup, A. Woods, Sefton (Golden-spangled). 2, H. Pickles. jun., Earby, Skipton. *hc*, J. Fielding, Newchurch (Silver-spangled); F. D. Mort, Stafford (Golden-pencilled); A. Woods (Silver-spangled and Silver-pencilled). *c*, W. Speakman, Nantwich (Golden-pencilled); H. Beldon, Bingley.

Polands.—Cup, W. Gamon. 2, E. Comber. *hc*, H. Pickles, jun.; W. Gamon; H. Beldon. *c*, T. Wakefield, Golborne.

Bantams.—Cup, G. Maples, jun., Wavortree (Black Red Game). 2, J. Crosland, jun., Wakefield (Black Red Game). *hc*, J. Halsall, Ince (Black Red); R. N. Barlow, Wrexham (Black Red Game). *c*, D. Young, Leamington (Black-breasted Red Game).

Ducks (Any variety).—Cup, T. Wakefield (Rouen—£7 11*s.* 6*d.*). 2, A. Woods (Rouen—£3 12*s.*). *hc*, E. Leech: Bowman & Fearon (Aylesbury); M. Gamon (Rouen); A Well-known Breeder (Rouen); R. Smalley (White Aylesbury and Black East Indian).

Game Cock (Any variety).—Cup, J. Wood (Brown-breasted Red—£12 2*s.* 6*d.*). 2, J. Statter. *hc*, E. Aykroyd, Bradford; Admiral Hornby (Red); J. Statter (Black Red). *c*, T. Myson.

Game Bantam Cock (Any variety).—Cup, T. Halsall. 2, G. Maples, jun. (Black Red). *hc*, T. C. & E. Newbitt, Epworth (Black Red); J. Crosland, jun. (Black Red); J. Statter (Duckwing); Bowman & Fearon; H. J. Nicholson, Holborn Hill, Cumberland (Black Red). *c*, H. Pickles, jun. (Duckwing).

Mr. Hewitt, of Birmingham; and Mr. Hindson, of Liverpool, were the Judges.

GLOUCESTER ORNITHOLOGICAL SOCIETY'S SHOW.

This Show, held at the Working Man's Institute, Southgate Street, Gloucester, opened on the 23rd inst., and will conclude this day. The *Cochin-Chinas*, Silver-spangled *Hamburghs*, and Rouen *Ducks* are very good, while among the *Pigeons* some of the specimens are excellent. The *Cage Birds* are of a very superior class to those commonly seen. The following is the prize list:—

Spanish.—1 and 2, D. Lane.

Dorkings.—1, E. Cooksey, Tuffley. 2, F. Gainer. *hc*, W. Stephens, Highnam.

Cochin-China (Any variety).—1, W. Sims, Stroud (Buffs). 2, G. Heath, Nailsworth (Buffs). *hc*, C. Taylor (Buffs).

Brahma Pootra (Any variety).—1, W. Sims (Dark). 2, C. Taylor (Dark). *hc*, J. Cooke, jun., Cainscross, Stroud (Dark); R. Blick (Dark).

Game (Any variety).—1, C. Taylor (Black-breasted). 2 and *hc*, J. Smart (Black Red and Pile).

Hamburghs (Golden, any variety).—1, R. Blick. 2, G. Heath.

Hamburghs (Silver, any variety). — 1, W. Stephens (Silver-spangled). 2, J. Aldridge (Silver-spangled). *hc*, J. Sallabank (Silver-spangled); J. Clutterbuck (Silver-spangled). *c*, J. Clutterbuck (Silver-spangled).

Polish (Any variety).—1, E. Cooksey (White-crested). 2, R. Blick (Golden). *hc*, R. Blick (Silver); W. Conway (Silver).

Any other Distinct Variety.—1, C. Taylor (Crève-Cœur).

COCKERELS.—1, C. Taylor (Crève Cœur). 2, G. E. N. Rawlinson (White Cochin.)

BANTAMS (Black-breasted and other Reds).—1 and 2, J. Mayo. *hc*, C. W. Washbourne; G. E. N. Rawlinson; D. Evans. *c*, C. W. Washbourne.

BANTAMS (Duckwings and other Greys).—1, J. Mayo. 2, C. W. Washbourne.

BANTAMS (Sebrights, any variety).—1 and 2, J. Mayo (Silver).

BANTAMS (Any other variety).—1 and 2, J. Mayo (Black and White).

DUCKS (Any variety).—1, 2, and *hc*, W. Stephens (Rouen).

PIGEONS.

CARRIERS (Any colour).—1, 2, *hc*, and *c*, J. Mayo (Black and Dun).

DRAGOONS (Any colour).—1, D. Lane (White). 2, F. G. W. Gainey.

TUMBLERS (Short-faced).—1, E. Stephens. 2, J. Mayo (Almonde).

TUMBLERS (Any variety).—1, E. Williams (Blue Balds). 2, C. W. Washbourne (Black Balds). *hc*, W. Stephens (White Rollers).

POUTERS (Any colour).—1, D. Evans (Red Pied). 2, W. David (Blue).

BARBS (Any colour).—1, F. J. W. Gainey (Black). 2, D. Evans (Black).

FANTAILS (Any colour).—1, E. Stephens, Ebley, Stroud (White). 2, F. Clark (White).

MAGPIES.—2, F. J. W. Gainey (Black and White).

ANY OTHER DISTINCT VARIETY.—1, C. W. Washbourne (Black Jacobins). 2, E. Stephens (Red Jacobins).

CANARIES.

NORWICH (Clear Yellow).—1, G. E. N. Rawlinson. 2 and *c*, W. David. *vhc*, R. Stone. *hc*, G. E. N. Rawlinson; J. Aldridge; R. Stone; W. David; J. Wood; G. Clapham, Upton St. Leonards.

NORWICH (Clear Buff).—1 and 2, G. E. N. Rawlinson. *vhc*, G. E. N. Rawlinson; J. Aldridge; W. David. *hc*, G. E. N. Rawlinson; R. Stone.

YELLOW (Ticked).—1, G. E. N. Rawlinson. 2, W. Williams. *vhc*, G. E. N. Rawlinson; J. Sallabank. *hc*, J. Wood.

BUFF (Ticked).—1, R. Woodward. *vhc*, J. Sallabank. *hc*, J. Wood.

YELLOW (Marked or Variegated).—1 and *vhc*, R. Stone. 2, G. E. N. Rawlinson. *hc*, R. Woodward; J. Sallabank; J. Wood.

BUFF (Marked or Variegated).—1, R. Stone. 2, J. Wood. *hc*, G. E. N. Rawlinson; J. Wood.

NORWICH.—*Clear-crested*).—1, R. Stone. *Clear-crested Buff*.—1, J. Sallabank. (Remarkably good crest.)

YELLOW (Variegated Crested).—1 and *vhc*, R. Stone. 2 and *hc*, J. Sallabank.

BUFF (Variegated Crested).—1 and 2, R. Stone. *vhc*, R. Stone; J. Sallabank. *hc*, J. Sallabank. (A superior class.)

BELGIAN (Any other variety of Yellow, Buff, or Variegated half-bred).—1, G. Clapham. 2 and *vhc*, J. Aldridge.

CINNAMON (Jonque).—1, R. Stone.

CINNAMON (Mealy).—1, R. Stone. 2, J. Wood.

CINNAMON (Any other variety of Yellow or Buff).—1 and 2, R. Stone.

BUFF OR MEALY PLAIN.—1, J. Wood.

MARKED OR VARIEGATED BUFF PLAIN.—1, 2, and *vhc*, J. Edwards.

MULE (Jonque Goldfinch).—1, E. Hopton. 2, J. Cox. *vhc*, J. Aldridge; R. Stone.

MULE (Mealy Goldfinch).—1, R. Stone. 2, J. Aldridge.

BULLFINCH.—1, G. Clapham. 2, J. Cox. *vhc*, R. Stone. *hc*, R. Woodward.

GOLDFINCH.—1, R. Stone. *vhc*, G. E. N. Rawlinson. *hc*, E. Hopton; J. Cox.

LINNET.—1, E. Hopton. *vhc*, J. Cox. *hc*, R. Stone.

SKYLARK.—1, *vhc*, *hc*, E. Hopton.

SONG THRUSH.—1, J. Hunt. *vhc*, G. Smith.

COLLECTION OF CANARIES IN CAGE.—1 and *c*, R. Stone. 2, J. Sallabank. *vhc*, J. Aldridge; J. Edwards; R. Stone. *hc*, R. Woodward; G. E. N. Rawlinson; J. Wood.

JUDGES.—*Poultry* and *Pigeons:* Mr. Yardley, Market Hall, Birmingham. *Canaries* and *British Birds:* Mr. George Moore, of Northampton.

INFLUENCE OF CLIMATE ON PLUMAGE.

I ENCLOSE a feather of a Dun Pigeon—it will be curious to mark the effect the climate has had upon the plumage, leaving a white margin almost around it. I have noticed the same effect in England, but not to so great an extent. I find fowls affected towards moulting time, much in the same way, and the wild Turkey even moulting darker than the old feathers. Taking all these facts into consideration, judges at shows should exercise discretion with regard to the points for plumage at autumnal exhibitions. People not aware of the effect of climate and light are very apt to be deceived in purchasing birds affected by this cause.

The bills, also, of Aylesbury Ducks and Embden Geese suffer much from exposure to the sun. Birds intended for exhibition should be sheltered during the very hot sun, and kept dark or in shade; but no amount of sun will bring black spots, which are a decided disqualification. These may, even in young specimens, be detected under the skin, of a reddish colour, and thus you are enabled to select those with pure-coloured bills, and reject the others for exhibition or breeding, making use of them for the table. But in spite of every inattention, a pure Aylesbury Duck will never get the orange bill of a Call Duck; a fact which should be impressed on inexperienced purchasers, because no common Duck can compete in any way with an Aylesbury.—F. C. H.—(*Canada Globe.*)

MR. PETTIGREW'S COMMUNICATIONS.

ALLOW me to join with the "DEVONSHIRE BEE-KEEPER" in expressing a desire that Mr. Pettigrew will continue his communications, for they have the rare merit of setting one thinking. And that they do good, is proved by the fact, that since Mr. Pettigrew ventilated the question of large hives last year, Messrs. Neighbour have considerably increased the size of their popular cottage hive.

I doubt not but a like beneficial result to the public will accrue from his drawing attention to the subject of spurious honey at this time. If anyone doubts whether supers can be raised successfully and profitably by means of sugar syrup, let him try, if he know how, and communicate the results to "our Journal" this time next year.—S. B.

QUEEN ENCASEMENTS.

IN the early part of 1865, some very able and interesting papers on "Queen Encasements," from the pen of Mr. Lowe, appeared in your Journal. It is there laid down as a rule, that these encasements continue for a period of from twenty-four to thirty-six hours, the latter being the longest which had been experienced by Mr. Lowe. The conclusions at which this gentleman arrived as regards the cause of encasements are shortly summed up thus:—

1st, That queens may be encased or imprisoned by reason of the entrance of stranger bees into a hive.

2nd, From superannuation and infirmity through age, or from any natural defect in their procreative powers, such as exhausted fertility.

3rd, Young queens may be encased or imprisoned when unfecundated beyond a certain age, and when in an abnormal condition.

A case in my apiary having lately occurred which, both as regards time and cause, cannot be accounted for on Mr. Lowe's theory, I am induced to forward to you the particulars, believing that they will prove interesting to apiarians in general. The facts are as follow:—

On the 1st of the present month I introduced to a strong stock of black bees, which had been deprived of their queen forty-eight hours previously, an extremely fine, healthy, and beautifully marked Ligurian queen, procured for me, from her native Alps, by Mr. Pettitt, of Dover. The method of introduction was simply that of presenting the queen through the central orifice in a Pettitt's bar-frame hive to her future subjects. I may here state that my reason for adopting so simple, and as some may think dangerous, mode of introducing a strange queen, was the loss of two Ligurian queens a short time previously by attempting to introduce them, in accordance with the usual plan, by imprisonment for twenty-four hours in a queen-cage. On opening the cages both queens were found dead, either from cold, as I imagine, or from being separated for so long a time from worker bees.

The queen was immediately imprisoned by encasement in the midst of a number of bees, so closely packed together in a small circular knot of about the size of a tennis-ball that it was impossible to get a sight of her, or to come to any other conclusion than that of her speedy death from suffocation. I determined, however, at all risks, to allow the bees to follow their own instincts, and on examination the following day, November 2nd, the encasement still continued. I now had the curiosity to separate the bees, which was effected with some difficulty, by means of a stout goose-quill, and to my surprise found the queen alive and well, although somewhat exhausted by the close embraces of her new subjects. After a respite of ten minutes, during which she was placed under a tumbler near the fire, the morning being very cold, the poor queen recovered her full powers, and was again introduced to the bees, again encased, again set free by main force on the day following, and, to render my story short, the same course was followed daily until Friday the 5th of November, on which day I had the pleasure of finding her at liberty, and receiving all due homage. After the first day's imprisonment I had noticed, on daily extricating this queen, that she was evidently well nurtured and cared for, and on finally obtaining her liberty was in fine condition, exhibiting evident signs of oviposition.

To what cause can we assign this long imprisonment? For my own part I am inclined to attribute it to extreme affection, and delight on receiving a queen after forty-eight hours' deprivation. Fear of again losing her, upon whom, as by wonderful instinct, the bees seem fully aware the future hopes of the colony depend, may also have influenced their actions. However this may be, there can be no doubt that their intentions were not regicidal, for their purpose was easy of accomplishment,

if such it had been, and there was no attempt to use the sting, or to seize the legs or wings of the prisoner—a usual mode of attack.

If any of your correspondents, skilled in apiarian science, can throw light on these mysterious queen encasements, they will confer, I doubt not, a favour on many of your readers who are interested in the natural history of the honey bee.

In conclusion, allow me to ask if it has ever occurred to modern apiarians that Virgil's beautiful description of the "*duo genera*" in Georg. iv., vv. 67-99, the—

> "Alter erit maculis *auro* squalentibus ardens,
> Nam duo sunt genera, hic melior, insignis et ore,
> Et rutilis claras squamis . . . . ."*

could have applied to the Apis ligustica, the modern Italian Alp bee? Several parts of his description would seem to favour this hypothesis. For instance, we have again—

> ". . . . elucent alvi et fulgore coruscant
> Ardentes *auro*, et paribus lita corpora guttis.
> Hæc *potior soboles*: hinc cæli tempore certo
> Dulcia mella premes; nec tantum dulcia, quantum
> Et liquida . . . . ."†

What more true and beautiful description could we desire of this exquisite variety of the Apis mellifica?—G. Raynor, *Tonbridge*.

SPURIOUS HONEY.

I extract the following passage relating to this subject from a private letter recently received from Ayrshire.—A Devonshire Bee-keeper.

Some one has been accusing us of giving our bees sugar to fill up their honeycomb with. I have made inquiries among some of the greatest bee-masters in this county, and they tell me that they have found out by actual trial that instead of imposing on their customers they would lose by it, for they say that they found it took 60 lbs. of sugar to make 20 lbs. of honey: so I think Mr. Pettigrew has found a "mare's nest." Honeycomb of the best quality is so cheap here (about 1s. a lb.), that it would not pay to make up a honey box with sugar. I had about 600 lbs. of surplus honey this last season, and I find the centrifugal machine is a great invention.—H. B.

* There are two sorts; the better glows with spots of gold, has a more beautiful person, and shines with bright scales.

† The others shine, and glitter with brightness, being spangled with gold and equal spots. This is the best sort. From this at certain seasons you shall squeeze sweet honey, and not only sweet, but pure.

OUR LETTER BOX.

Hens Eating their Eggs (*M. Y.*).—The habit is supposed to arise in the first place from the lack of the necessary material for forming the shell of the egg. It is in this case prevented by supplying their run or house with plenty of bricklayers' rubbish, such as old ceilings, mortar, &c. If they have this and still peck their eggs, it is from a bad state of the body. The only cure we know, is to put some very hard composition eggs in the nest. They peck them till their beaks are sore, and become tired of it. But prevention is to be preferred, therefore we recommend to your attention the form of nest described by a correspondent in our Journal to-day.

Chester Poultry Show.—Mr. Eggleston, Savile Mills, Halifax, informs us that he took the first prize for English Owls; Mr. Graham, second; and Mr. Crosland was not mentioned. Mr. Walters has sent us a letter he received from the railway office relative to the charge of an extra sixpence. The charge was made by Chaplin & Horne for conveying the birds from the Show to the station, and the Committee of the Show had not undertaken to deliver them free from charge.

Roup (*T. Y. P.*).—Extreme cases should be treated with Baily's pills, but incipient cases, which are very often only bad colds, may be cured by giving camphor pills, two the size of a pea for a dose, and feeding for a day or two on bread and ale.

Wortley's Incubator (*Inquirer*).—You should inquire of Mr. Crook.

Barren Aylesbury Ducks (*Perplexed One*).—If you know the Aylesbury Ducks are barren, they are not such as should be shown. We have, nevertheless, no doubt that more than half the very heavy Aylesburys are certainly barren, and many of them known as such. We do not believe your Ducks are barren; if you were to tell us you founded your opinion on the fact that they did not breed this year, we would advise you to try them next year with another drake. The drakes are very often barren from accident. If you are sure that your birds are barren, do not send them. We are decidedly of opinion that they are not, and, therefore, we should not hesitate about exhibiting them.

Dark Buff Cochin Plumage (*A Subscriber*).—The under tail of a Cochin hen is always dark, almost black. In both cock and hen a buff tail is preferable.

Houdan Cock's Spine Injured (*Chemicus*).—The cock with infirm gait and now contracted feet is injured in the spine; that causes the contraction and partial paralysis. It is generally fatal. The treatment will be to put the bird in some place where he can have the flooring covered with hay or straw, to feed well, and, above all, to administer stimulants—ale, camphor, and sometimes a table-spoonful of port wine. This paralysis must not be confounded with the weakness to which heavy birds are subject from over-growth. That, if the birds are well treated, is cured from the day the bird ceases to grow. The slightest blow on the back of a fowl will cause paralysis and often death. Crooked breast-bones are often hereditary, and sometimes caused by roosting. Fast-grown chickens are weak and often too heavy for their half-formed leg-bones. This induces them to rest on their knuckles on the ground by day; but at night, when perching, their legs are not strong enough to hold them steadily on their perches, and they are obliged to allow their breasts to rest. If, then, the perch be small, the cartilaginous bone of the breast is susceptible of change, and takes the form of a narrow perch. The cure is to put one some inches in width.

Fowls in Confined Space (*E. J.*).—You can keep either Cochins, Brahmas, Spanish, Houdans, or Crève-Cœurs. Our experience is, they bear confinement better than the Hamburghs. Only the first two of those we have named are sitters. The Pencilled Hamburghs are called everlasting layers.

Feeding Golden-spangled Hamburghs for Exhibiting (*For West*).—Ground oats mixed with milk, occasionally a few peas and some bread and ale, a little whole barley once per day. If it is not in their haunts they require green food, and should have daily a large sod of growing grass cut with plenty of mould.

Southampton Poultry Show.—We are informed that the second prize for Light Brahma chickens was awarded to those of Mrs. Turner Turner, Avon, near Ringwood.

Houdan Cockerel with Crooked Breast (*C. J. S.*).—Most certainly we should not breed from such a bird. Crooked breasts and wry tails we know to be hereditary defects.

White Muscovy Ducks (*R. O. P.*).—The White variety of the Musk or Muscovy Duck would be profitable to keep if there were any market for the produce, but they are birds that are seldom wanted or asked for. They are scarce. The habits of the drake of all colours of this breed are sufficiently objectionable to banish him from all yards and ponds. They are not so prolific layers as other Ducks, and we consider them unprofitable.

Pigeons Healthy or not (*Foncier*).—The bird may be of a very wild nature, hence its quick breathing and death-like fright when caught. Without seeing it no one could properly decide whether it is diseased or only very timid. We advise you to ask some independent fancier or judge in your neighbourhood to decide the point, but we incline to think it healthy.

Feeding Beans for Exhibition (*N. A. D.*).—Good old beans are best as they brighten the plumage; a little old wheat mixed with them would do no harm. The beans must be small.

Matching various Pigeons (*H. T. Kelsey*).—The advice we gave you recently is applicable to the Black hen Barb being crossed with a Red cock. The matching a Yellow Fantail with a White would spoil both. Colours, like breeds, are best kept distinct.

Pigeon Shot, &c. (*A Young Beginner*).—Sue, in the County Court, the person who shot your Pigeon for the value of bird. Antwerps would suit you best for homing from a distance, or Dragoons.

Food for Grey Parrot (*Peter*).—Bread and milk are the best food. Cut the bread in slices, and pour over it warm water; let it soak a short time, and squeeze it as dry as possible; then allow it to absorb as much fresh boiled milk as it will without being too moist. Give occasionally broken biscuit, nuts, and fruit; sometimes, though not often, boiled Indian corn when cool. Never give a bone or any meat, for it brings on a disease which impels the bird to pull out its feathers. Hempseed and other seeds are quite unsuitable for all the larger Parrot tribe, and do not give them to the Grey Parrot. The cage smelling sour arises from the pans not being scalded every day. Your bird will talk a little at a year old, and improve every year.

Rabbit with Scabbed Head (*A Subscriber, Nantwich*).—"Very frequently the mischief arises from fleas at the top or back of the head, where they most congregate, and eat into the flesh. They will give the appearance of scurvy, and the Rabbit's scratching will keep this up sometimes long after the fleas from cold or other causes have taken their departure. For the destruction of fleas there is nothing so perfectly harmless and so thoroughly effective as Keating's Insect Powder: one good rubbing with it is sufficient to destroy them all in a day, and if the hutch be well cleaned out at the same time there may be a long interval of rest. If, however, the owner is sure that these scabs have come of their own accord, it is, no doubt, scurvy, and this can only be cured by giving them less dry food and more soft. On some Rabbits too much dry food acts as too much salt meat does with our sailors—the want of sufficient vegetable is the evil. No barley or peas should be given, and even oats should be gradually discontinued, and bran take its place, at least for a time. A mash of thirds, with unground linseed and tea-leaves in it, made into the consistency of paste, and about as much as could be held in the hollow of the hand, is an excellent breakfast for Rabbits under any circumstances, and is greatly used by the London men. The best local application is olive oil for two or three days, the part then to be washed with thick soft-soapsuds. The scabs will then come off, or will do so if this course be repeated.—B. Hudson, *Hull*."

Shelter for Bees (*Learner*).—We should prefer the aviary to the greenhouse, making good-sized semicircular apertures in the wirework opposite the entrance to each hive.

Mulberry Wine (*Morus*).—We advise you to leave the wine undisturbed until it become fine. This can be ascertained by having a peg in the centre of the head, and drawing a little of the wine out into a glass once a-month. When it has become quite clear, rack it off again without disturbing the lees. Let it remain for a week or two, and then bottle it. The bottles should be placed on their sides.

Rhubarb Wine (*Amicus*).—We do not think the "slightly putrid flavour" was caused by washing the cask with rain water. Put some lumps of charcoal into the cask, and shake it repeatedly at intervals of a day or two, and when clear again rack off before bottling.

Douglas's Mixture (*W. I.*).—We know nothing about it.

From observations taken near London during the last forty-two years, the average day temperature of the week is 47.7°; and its night temperature 35.2°. The greatest heat was 61°, on the 4th, 1857; and the lowest cold 13°, on the 8th, 1857. The greatest fall of rain was 1.02 inch.

WINTER BEDDING PLANTS.

NOT without some feeling of disappointment, I read your report of the plants exhibited lately at the Royal Horticultural Society's meeting for the prizes for the best collection of winter bedding plants. Having advocated for many years the claims which winter plants have as compared to spring ones, I felt anxious to learn what class of plants might be recommended for the purpose by those to whom we may fairly look to be leaders in such matters; and I cannot but regret that more collections than one were not sent to the meeting; for, without in the least disparaging the class of plants described by you as taking the first prize, I fear the general public are not yet in a position to patronise choice shrubs and Conifers for winter decoration. Plants less costly, and involving less labour during the season when their services are not wanted, appear to me more likely to meet the requirements of the majority of cultivators. All of these have not the means of obtaining Hollies, Aucubas in berry, or Japanese Conifers, and yet would like to have their flower beds ornamented from November till March or April; and I would have been more glad had collections been exhibited such as persons of moderate means could have stocked their beds with at a cost not greater than that which is requisite to do so in May. Now, with the costly plants to which Mr. Wilson Saunders' prize was awarded, the expense of winter decoration must be at least fourfold that for ordinary summer bedding plants, assuming both are to be purchased in the usual way. Even assuming the winter decorative plants to be made to do duty for two or three years, still the trouble and expense in keeping a large collection of plants over the summer in pots will be quite as great as in wintering and propagating Pelargoniums, Verbenas, Calceolarias, and the like. I fear, therefore, only the most affluent will be inclined to patronise the costly collection, and the less fortunate will have to be satisfied with a more homely list, or dispense with winter decoration altogether. To assist the latter in making a creditable display at a small cost, I beg to offer the following observations, not with any intention of disparaging variegated Hollies, Osmanthus, Aucubas, and choice Conifers, but to show that a tolerably good effect can be produced without incurring the expense which Conifers, &c., entail.

Before entering on the description of the rather meagre list of plants I have generally been satisfied with, I may say that I am no advocate for great variety either in summer or winter bedding, and I have sometimes been thought, in carrying out this view, to go to an extreme when using only four varieties of plants for two beds or borders containing upwards of a quarter of an acre of ground (or a space equivalent to about 150 circular beds, each of 10 feet in diameter); yet I do not think that any one who saw them considered the effect could be improved by more variety. It is the same in winter gardening; a few effective plants do more service than the most choice collection when too much mixed, unless it should happen that the bed they are placed in should be so close to the eye that every leaf and feature of each individual plant will be under the eye. In the latter case each plant may be scanned in the same way as the occupants of a conservatory shelf or greenhouse stage; but where flower beds at the distance of 50 yards or more have to be filled, the number of species used must be very limited, or a sort of chaotic confusion will be the result. Although there may be cases where a departure from all rules that can be laid down will be necessary, I would venture to say that a better result would follow planting all beds under 10 feet in diameter or width with only two kinds of plants, than with a larger number, one of these plants being suitable as an edging, the other being used to fill the body of the bed. If the bed be a circular one, the presence of an upright central plant, as a Yew, Cypress, or something of that kind, might perhaps be advisable, but I am not certain that small beds require this.

Another point necessary to bear in mind in the winter arrangement of flower beds, is the fact, that the surface of the ground is expected to be for most of the time in a moist state, and consequently darker coloured than it is in summer: hence the advisability of using as many plants as possible with light foliage in preference to those with dark leaves. The advantage of this is especially seen in the case of low-growing plants, where their contrast with the naked soil, or it may be the surrounding turf, is seen to advantage. The number of plants available for this purpose is sufficiently large for all reasonable requirements, and their plentiful use cannot be too strongly urged. Dark-leaved plants, on the contrary, however ornamental at other times, are seldom satisfactory in winter. This fact I proved some years ago by trying the effect of some fine coloured Beet one autumn, but it was a failure; the absence of the sunshine, so necessary to bring out the bronzy hue of the leaves of the Beet, rendered them ineffective, and the imprudence of depending on colours so much approaching that of the earth became evident. Some shades of green come out better.

As economy is the assumed qualification of the plants to be recommended, it may be stated here that one of the greatest merits the plants possess is the ease with which they are transplanted twice a-year, with a few exceptions, and with but slight loss; for, be it remembered, pots are entirely dispensed with, and only such plants recommended as will bear transplanting in autumn with little or no damage to themselves, and if they do not survive transplantation in the spring, they are expected to be of such easy propagation and growth as to be no serious loss; for it must be observed that many plants do not succeed well when removed at the latter season, and losses will occur. Where there are the means, however, of bringing on a number of younger plants for the next season the loss of overgrown ones need not be thought seriously of, for it often happens that some places in the shrubbery may receive those cast away, and their after-growth can be turned to good account. Some of the smaller specimens, too, might be returned to the reserve ground to serve for a

similar purpose another year; at the same time it is advisable at all times to have a set of young plants coming on.

One of the best qualifications a plant can have for the object under consideration is that of lifting well with a good ball of earth adhering to its roots. Amongst shrubs, Box and Aucuba are, perhaps, the best; while among Conifers, some of the Cupressus tribe are very indifferent. Most of the Arbor Vitæs transplant well, and so does the Irish Yew, while the Wellingtonia is not by any means good, neither is it a suitable winter plant. One of my greatest favourites is Retinospora ericoidea, but of this hereafter; suffice it to say that a plant which transplants well, and with a good ball of earth to its roots, is, if other points are favourable, a suitable one for winter. Another qualification is hardiness. I have never been able to see some of the merits of so-called winter plants as respects their berry-bearing or flowering properties; their flowering is rarely satisfactory till March, and in most country places the small birds make short work with the berries. In mild winters, however, Primroses and the like sometimes flower during winter, and the berries of Cotoneaster, Yew, and some other shrubs may be allowed to hang, but they are not sufficiently numerous to show at all at the distance of a few yards, and, consequently, it is upon foliage that we must depend for what display there generally is between the 1st of November and the middle of March, or a period of between four and five months, and often longer. It is, therefore, with a view to give a cheerful appearance to ordinary flower beds during that inclement season that the following list of plants of easy culture is recommended.

Helleborus fœtidus.—What is this? I have been asked many a time by plant-growers of eminence, who, struck by its appearance, declared it capable of taking its place amongst collections of fine-foliaged plants at exhibitions. I must tell them it is said to be a British plant, although I cannot say I have ever met with it in a position where it could be considered truly wild. In some moist places, however, it has the appearance of being the outcast of a garden, although its very name is all but disavowed by the gardeners of the present generation; yet many old plants have been called into requisition again, and so will this, I imagine, when its merits become better known. In Hooker's "British Flora" it is said to be found in pastures and thickets, especially in a chalky soil, to have leaves pedate and evergreen, and to flower in April; it is also described as powerfully cathartic. Now, without going into the botanical and chemical description of the plant, I may say it is an evergreen bush from 1 to 2 feet high—quite the latter height when flowering—its dark green foliage bearing a strong resemblance to that of some of the exotic Palms belonging to Chamærops or Latania, and the leaves are sufficiently plentiful to hang down to the ground gracefully on all sides of the plant. From the top of each stem (if it have more than one), rises a large cluster of pale greenish-yellow flowers. Many of the plants here are showing flower now (the middle of November), and the flowers are often fully expanded by the end of January, and their presence does not by any means diminish the beauty of the plant.

It transplants as well as a Box or an Aucuba, its roots being so numerous, and all extending about the same distance from the collar. It is a very effective vase plant, its graceful foliage and uniform growth fitting it well for the purpose, while its hardiness enables it to bid defiance to the cold winds and frosts of winter, which few plants will do in such a situation. In very severe frosts its foliage will hang down, and so does that of Laurels and most shrubs, but it recovers its position again when mild weather sets in. The plant is by no means very choice in respect to the situation in which it has to pass the summer; a shady spot under trees, where many other plants refuse to grow, or an indifferent piece of ground in the full sun, is equally acceptable. Its propagation is easy, as it seeds abundantly; but I may here caution the inexperienced not to be too hasty in censuring the seedsman if the plants do not come up so soon as expected, for there are few seeds which lie longer in the ground than those of this plant; but if not disturbed they will germinate in time, or even if they be dug in not too deeply, after the patience of the cultivator has been exhausted in waiting for them, it is not unlikely that the next year may witness the seedlings coming up in abundance. The same may be said of seed sown in pans or boxes, and kept in a warm place until all expectation of its germinating is at an end. When the contents are emptied on a vacant place in the kitchen garden, good plants are likely to be discovered there afterwards.

When once the plants have made their appearance above ground, I do not think they are in much danger from anything excepting the hoe and other garden tools; insects seem to be scared away by the fœtid smell, and the plants will struggle for an existence amongst most of the occupants of the garden. Their growth, however, is not rapid until the dews of autumn set in, when the plants grow faster, and a plantation of a few hundreds of them has a neat appearance. In general, I plant the small plants in rows about 18 inches apart, and half that distance from each other in the row, and they form fine bushy plants when taken up in the autumn. A few larger plants for vases and special purposes are placed farther apart, while seedlings that are too small to be of service the first year, may be kept closer together till spring. It is very accommodating, and a plant or two in an out-of-the-way place will supply all the seed that is wanted. To those who have never yet grown this Hellebore, I would recommend it with every confidence that, when once they have a supply of it, they will not exchange it for anything else.

Aranis albida variegata.—Amongst low-growing light-coloured-foliaged plants, I confess this has been my favourite for many years; possibly this may arise from the soil and other circumstances suiting it. Its relative, A. lucida variegata, has been just the reverse, and I have never been able to do anything with it; the former, therefore, does much of the duty of edging. For this purpose rooted plants are not by any means necessary in autumn, but the long side shoots pulled off overgrown plants are merely laid in like so much Box or Thrift edging, and in the spring every piece is found rooted; but stocky plants from 6 to 12 inches in diameter are sometimes used, and as these can be taken up with balls of earth, they transplant without any loss, and there is something so effective in the soft clear cream-coloured hue of this plant, that I have not yet met with anything that equals it for general effect when seen at the distance of a few yards. Even nearer it loses none of its beauty, and is altogether indispensable as a winter bedding plant. As a permanent plant it is likewise useful, and I have employed it as such for upwards of fifteen years, but I find that, like many other plants, it does not succeed well if grown continuously in the same place; in other respects it is very accommodating, and is, I consider, a first-rate winter bedding plant.—J. Robson.

(To be continued.)

AMONG THE ROSES.

Since "our Journal" aroused rosarians week after week, the lovers of "our queen of beauty" have been gratified with jottings which have not only added considerably to our Rose lore, but have also attracted the attention of many who had not previously taken a lively interest in our favourite flower. I can testify—and it gives me great pleasure to be able to do so—that in this part of Warwickshire, bleak as to climate and sterile as to soil though it be, the cultivation of the Rose is making rapid strides amongst the latter class of florists.

During the autumn Xavier Olibo has proved itself to be first-class. Its colour has been rich in the extreme; it has bloomed continually, and never failed to produce a full flower; in the latter respect the autumn blooms have surpassed the summer ones. Its free form also renders it a great favourite of mine, and I know of no sweeter pleasure than to view in the early morn a dew-bespangled bloom of Xavier Olibo glistening in the rays of the rising sun.

The more I see of the Duc de Welltington the higher its splendid qualities raise my admiration. Its form is good, its colour gorgeous, and in the duration of its bloom it is certainly unequalled: pity its growth is not vigorous. Duchesse de Medina Cœli now and then brings forth a flower of dazzling hue. For this quality alone it is well worth growing, although the bloom is only small, and far from being full. Horace Vernet is a Rose, which for the brilliancy of its colouring and the charming perfection of its form, may be placed first in the ranks of the velvety class. It will soon be as well known as Charles Lefebvre. Souvenir de Comte Cavour is another of the dark crimsons which has done well this autumn. I shall pay more attention to it, and propagate it more than I have hitherto done.

The above, with the well-known Duc de Cazes, make half a dozen of the dark velvety class which are worth all the pains we can give to their successful culture. Pierre Notting, although a perfect-shaped flower, and as dark as any of those I have mentioned, lacks the beautiful bloom which they possess, and in consequence has a dull appearance, otherwise it would be my *beau idéal of* a dark Rose.

Alfred Colomb is always bright and full; summer and autumn alike it never fails to show itself a first-class Rose. What a triumvirate it, Charles Lefebvre, and Marie Baumann make! and who will dare to say which is the foremost? I think the Comtesse de Jaucourt must no longer be catalogued as a first-class Rose. It is just worth a place in every rosery, and that is all that can be said in its favour. Madame Furtado, during the intense heat of 1868, bloomed incessantly with me, and those who have seen a good specimen of this Rose know what a ravishing beauty it is. During the past season the blooms have been miserably bad. Such are the effects of different seasons!

Ophirie, a Noisette, is a singular Rose, of a peculiarly bright salmon tint. It is hardy, and although not full, makes a pretty buttonhole flower.

I had grown Semiramis for two years without knowing its beauty until this season. When planted in strongly-manured ground it is really a free bloomer, and very full; its colour is pure pink. As a matter of course it is far surpassed by Marguerite de St. Amand, and especially by Monsieur Noman, in my humble opinion the best pink Rose in existence. Chevalier Nigra and Centifolia rosea surprised me this autumn with fine blooms; the latter is only wanting in fullness to make a good Rose. Lord Raglan and Madame Moreau have done no good. Mildew settled upon them early in the season, and stuck to them until the last. I find that others have had a like experience.

Climbing Devoniensis has disappointed many by reason of its rampant growth unaccompanied with flowers. I notice that a contributor to one of your contemporaries states that even when the leading shoot is stopped the growth of flowering laterals is not thereby induced. If this be its general character it is much to be regretted, for a lovelier hardy Rose does not exist. Not only is its shape a fine deep one, and its colour pure and lovely, but its perfume is exquisite. In stating this much I speak from experience, for during the past six weeks a single shoot of this noble Rose has afforded me a flower for my buttonhole at least twice a-week, and there are still nine buds to expand. It is budded on a rampant climber, called in Yorkshire "Wood Superb," and has this season thrown up a single shoot without a lateral, 8 or 9 feet high, and crowned with buds. I did not cut away the other wood of the stock, but let all grow: the result is that the Devoniensis shoot is only one of a dozen equally thick but not so long as it is. I shall try other Tea Roses on this stock.

A week ago I bought about fifty Roses, among them was Marie Baumann, the most highly prized of the lot. Although I had not previously possessed it, I knew it well—literally by heart, and therefore planted it with extreme care, looking forward through many dreary months to the time when she would

"Greet me with a smile at morn;"

but, alas! while I slumbered some dainty rascal robbed me of my treasure, and the morning after it was planted I looked in vain for my pet lamb. I cannot even supply its place, so great has been the demand for this gem.

My standards ceased to bloom upwards of a month ago, but the Manetti-stocked Roses are blooming still. Altogether my experience of the season passing away has added strength to my previous conviction, that the Manetti Rose stock is alone worth cultivating in this part of the country. This opinion I have freely expressed to those who have consulted me on the subject of stocks, and as a result, my neighbours have bought standards merely when required for ornamental purposes.—C. W. M., *Wylde Green.*

HOW WE GOT OVER OUR PEACH FAILURE.

As with many others, our Peach crop was almost a total failure. How we were to tide over September, and especially "t' Leger week," was a problem disagreeable to contemplate. Grapes, &c., we could furnish in quantity, but the absence of Peaches and Nectarines would be too conspicuous.

Our first and second early crops were plentiful and excellent, and we were congratulating ourselves on this, and thinking it would to some extent compensate for the scarcity in autumn, when just as the first house was about finished, and the second and best house about coming in, it was intimated to us, that in consequence of the movements of the heads of the establishment, the fruit would not be required for home consumption. This was mortifying; selling was unsatisfactory; but how could we keep them from the middle of July till the end of September? Could we put them in ice? No sooner said than done. The same circumstances which had necessitated this step had also set our London tin packing boxes at liberty, and they were put in requisition directly. A sheet of cotton was laid in the bottom of each box, and the Peaches and Nectarines were pulled as they ripened, and laid in the boxes without packing, but as closely together as they would go without touching each other. The boxes were then shut down closely, and conveyed to the ice house, where a level trench about 2 feet deep had been prepared for them, on the top of the ice, in which they were set, also several boxes of Pines that had already been standing ripe for three weeks in a cool house. Farther than an occasional look to see if all was right, the fruit was left undisturbed till the end of August, when the first demand was made upon it. The Peaches were then as sound as when pulled off the tree, and the flavour as perfect; Pines also were quite sound. The last of the Peaches and Nectarines were used about the 20th of September. The Peaches were a little tender in the skin, but otherwise excellent; the Nectarines (Victoria) were perfectly fresh, and to all appearance would have kept till Christmas. I may mention that towards the middle of September I exhibited some of the same Peaches and Nectarines, and obtained first prizes for them against autumn-grown fruit. Hitherto we have kept our Lady Downe's and other Grapes on the Vines, but if needful would resort to the same plan with them, only we would hang them in boxes set on edge.

Now, this is one advantage of an ice house which I do not suppose your readers to be ignorant of, nor do I claim originality in the plan, but only state my experience in the matter, as a reminder to those who may be similarly circumstanced.—J. S. W.

DAHLIAS FOR A SMALL GARDEN.

I HAVE read Mr. Witherspoon's letter in No. 450 on the advantages of small gardens, and I may say that I am always thankful for any information respecting the culture of flowers and vegetables, a mixture of which it is pleasant to cultivate. He asks for some information about the Dahlia. I have grown Dahlias and exhibited them as an amateur at many of the principal shows in the north with varied success for the last ten years, growing about eighty plants yearly, consisting of from thirty-six to forty-four varieties. I think that no amateur can grow more to do justice to them unassisted, which all amateurs should be. To have any chance of showing twelve dissimilar blooms fit for exhibition, I imagine he should not have less than sixty plants. I should divide them into thirty-six varieties, growing three plants of each of the best six varieties, two plants of each of the twelve next best, and eighteen single plants of different kinds, altogether sixty plants. I do not think that an amateur can have any chance of success with less than this number, as nurserymen's assistants show flowers only a shade inferior to their masters, and flower-show committees take little notice of them, for I know some committees which have had information about nurserymen's assistants exhibiting Apples, Pears, Plums, Roses, Hollyhocks, and Dahlias, although growing nothing in their gardens but about three dozen Dahlias and a few Potatoes. These men always take the head prizes at the shows, and genuine amateurs, who grow for pleasure, have to be content with prizes lower down the list, or nothing at all—a state of things that will soon work its own cure.

I shall now give a list of the best thirty-six varieties of Dahlias that I have grown, all old ones, as I seldom purchase the new sorts till the second year of their being in commerce, consequently I cannot speak for them till I have grown them; although there are six varieties which came out this year that I intend to procure—viz., Emperor, Memorial, Annie Neville, King of Primroses, Golden Fleece, and another sent out by Mr. Turner, of which I forget the name—all good sorts, from what I have seen of them when exhibited by nurserymen this year. My list of old sorts is as follows:—

Vice-President	Lady J. Ellis	John Kirby
Lord Derby	Bob Ridley	Flambeau
Miss Henshaw	Yellow Perfection	Andrew Dodds
Criterion	Mrs. Dorling	Rosy Queen
Harriet Tetterell	Delicata	Alexandra
Leah	Favourite	Lord Palmerston
Imperial	Bullion	Lady Gladys Herbert
Chairman	Princess of Wales	Earl of Shaftesbury
Autocrat	Miss Roberts	Lady of the Lake
Vidette	Mrs. Thornhill	British Triumph
Adonis	Hugh Miller	Valentine
Purple Gem	Lady Derby	Mrs. Boston

Mrs. Boston is one of the best, if it can be had as good as

I have seen it shown by some amateurs from near Bedale, but I have grown two plants each year for the last two years, yet have not had a flower fit to exhibit. There are many more good sorts which I have grown, but they are so inconstant as to be of no use to an amateur, sometimes producing not one good flower in a season.

My method of cultivation is to obtain strong plants by the last week in May, and then plant them out; watering them overhead twice a-week, or oftener, if the weather be very dry, and thinning the lateral shoots out as soon as they are an inch long, taking two shoots out of every three in the case of medium-sized flowers, and with large flowers less, supplying the plants when making their flower buds with a drenching of liquid manure once a-week, besides washing them overhead with clean water every night to keep thrips off the flowers. By following out this plan, an amateur can cut twelve or more dissimilar varieties any time from the middle of August to the end of the season—that is, if the land be well manured and trenched to begin with.—JOHN HILDRETH.

APPLICATION OF MANURES.

NOTHING is easier for any person fond of reading than to get up an orthodox opinion on any well-discussed subject. It is only when we think for ourselves and advance independent ideas we get into trouble. Unfortunately it is not every one who can bow to authority on purely scientific subjects, and though chairmen can do no wrong, and editors are supposed to know everything, I am more than ever convinced that unfermented manure loses nothing by sun and wind. For have I not been answered by our Editors? Has not every argument that could have been advanced been recorded against me by the highest authority? If these have not carried conviction, what more can be expected?

With the excellent directions for preparing fermented manure we have now no concern, because that is not now the question, nor whether my opinions accord with those of Professor Johnston and of Davy, with whose works I am well acquainted, but whether unfermented manure loses anything besides water by exposure to sun and wind. The Editors say fresh pigeons' manure, fowls' manure, and sheep's manure are stronger than old, which is just begging the question; that fresh guanos are richer in ammoniacal salts than those long exposed to the sun, which is again begging the question, or, at any rate, taking the cause of loss for granted. Johnston says, "Pigeons' manure when exposed to moisture undergoes fermentation, and loses a portion of ammoniacal salts;" "in warm climates pigeons' manure dries rapidly, and may be kept for a considerable time without losing its fertilising virtue" (see page 801 of his "Lectures on Chemistry"). "During the putrefaction of urine the greatest part of the soluble animal matter that it contains is destroyed; it should consequently be used as fresh as possible" (Davy and Shiers, page 231).

These extracts do not look as if the authorities quoted could be well cited against me; but if your readers will turn to the seventeenth volume of the Royal Agricultural Society's "Journal" they will find a long and interesting essay on farmyard manure by Dr. Augustus Voelcker, from which I will make a few extracts, though I would advise everyone to read it for themselves. "Perfectly fresh manure contains but a small proportion of free ammonia." "The nitrogen in fresh dung exists principally in the state of insoluble nitrogenised matters." "The most effectual means of preventing loss in fertilising matters is to cart the manure directly on the field." "On all soils with a moderate proportion of clay no fear need to be entertained of valuable fertilising matters becoming wasted if the manure cannot be ploughed in at once." "Fresh, *and even well-rotted manure* contains very little free ammonia, and since active fermentation, and with it the further evolution of free ammonia, is stopped by spreading out the manure on the field, valuable volatile manuring matters cannot escape into the air by adopting this plan." "It may indeed be questioned whether it is more advisable to plough in the manure at once, or to let it lie for some time on the surface, and to give the rain full opportunity to wash it into the soil." "In the case of clay soils, I have no hesitation to say the manure may be spread even six months before it is ploughed in, without losing any appreciable quantity of manuring matters." "During the fermentation of dung ulmic, humic, and other organic acids are formed, as well as gypsum, which fix the ammonia generated in the decomposition of the nitrogenised constituents of dung."

I sent the three numbers containing this controversy to a gentleman well known as a first-rate analytical chemist, and asked him to forward his opinion on certain questions, which I wish you to publish, though, as I have not his leave to give his name you will please not insert it. I received Dr. Voelcker's essay, from which I have made these extracts, since writing the first part of this paper, and certainly was pleased to find I was so borne out by such an authority.

Mr. Rivers, in a letter received some time since, says he not only agrees with me, but practises the same plan of manuring. I may now be permitted to say, that when old guano is less valuable than fresh, it is due to rains having fallen upon it, or damp having caused fermentation, and the same with the dung of the sheep or pigeon; and that I was quite surprised to see the loss of carbonic acid mentioned—first, because it is impossible to occur in the absence of fermentation, and, secondly, it would be little loss if it did. I hope at least that your numerous readers, whichever side of the question they take, will give me credit for not advancing opinions without some consideration, and that the Editors will excuse my differing from them in the matter.—J. R. PEARSON, *Chilwell*.

The letter Mr. Pearson enclosed is as follows:—"In answer to your inquiries I beg to give you as my opinion—

"1st, That no carbonic acid would be lost by spreading fresh manure upon the land. The loss of carbonic acid occurs in the manure heap several feet in thickness where active fermentation is going on.

"2nd, Ammonia is only present in unfermented dung in very, very small quantity.

"3rd, Uric acid in manure would not be dissipated unless the manure were in an active state of decomposition. Spread thinly over the soil, no loss would be sustained.

"4th, Uric acid will be turned into ammonia only by the process of fermentation.

"5th, Heavy showers and fermentation have more to do with the depreciation of guano than sun and wind. In moist climates the ammonia is all washed out, and nothing but the phosphate left.

"There is an old adage—

> "'Be it wet or be it dry,
> Spread your muck and let it lie.'

After which, in my opinion, it is best to be ploughed in as soon as convenient."

[We remain of the opinion we expressed, and consider that exposing spread stable manure for a lengthened period to the sun and wind deprives it of some of its fertilising constituents, and that by such exposure it cannot gain anything. The other examples we quoted of animal dungs, we consider illustrations of the consequences of exposing such excretions for a long time until they have become as dry as sun and wind can make them. We will pass over what Prof. Johnston states about the waste from allowing long dung to remain on the surface of the soil, and what Davy says about keeping dungs from exposure to the air; and we will proceed at once to the quotations from Prof. Voelcker's well-known communication to the Royal Agricultural Society. He says, "Perfectly fresh manure contains but a small proportion of free ammonia." What becomes of that proportion when the manure is exposed until it is dry as sun and air can make it? Why, it is dissipated and lost, which would not have been the case if the manure had been ploughed or dug in. When Professor Voelcker speaks of no fear of waste if the soil contains clay, he only refers to what is washed into the soil by the rains. So, when the Professor observes that active fermentation and the evolution of free ammonia are stopped by spreading out the manure, he does not proceed to say that it loses nothing but water, as Mr. Pearson implied, if it be left exposed on the surface. We quite agree as to checking fermentation, but we add, spread and plough or dig in at once, if only to save the "small" amount of free ammonia. Professor Voelcker says no more than that it is to be "questioned whether it is more advisable to plough in the manure at once, or to let it lie for some time on the surface, and to give the rain full opportunity to wash it into the soil;" but with all the well-deserved deference we feel for the Professor, we cannot perceive why all risk of loss should not be avoided by burying the manure at once in the soil, instead of waiting for it to be washed in by the rain. The Professor adds, "that exposure for six months on the surface would not cause the loss of any appreciable quantity of manuring matters," but he confines this to "clay soils," and therefore refers to the soluble matters washed in by the rains. The "small" proportion of free

ammonia must have been lost. We pass by Mr. Pearson's observation that fresh guano is richer in ammonia than old guano, because the latter has been more exposed to the rains, although that is not correct, the guano latitudes being characterised by a singular absence of rain, but the ammonia would be diminished, as he rightly observes, by fermentation. He is not correct in saying that carbonic acid would be little loss, because experiment shows it is beneficial when applied to the roots of plants, and he is equally incorrect in stating it is impossible to occur in the absence of fermentation—an old stick in the process of decaying emits carbonic acid, and decay commences in a straw as soon as it is dead and damp.

The letter from the clever chemist which Mr. Pearson appends, needs little comment. The two first paragraphs in it are replied to in what we have already said. We never stated, nor thought, that the uric acid of urine would be dissipated by its exposure to the sun and air, but urine rapidly decomposes, and what becomes even in the freshest stable litter of the free ammonia so rapidly developed from the urine of the horse that it has to be fixed by gypsum or other agent in order to render a stable's atmosphere healthy? With the last sentence in the letter, "In my opinion it [muck] is best to be ploughed in as soon as convenient," we fully concur, adding only, we would not put it on until it is convenient to plough it in.

How much stable manure loses by long exposure to the sun and air will never be known decidedly until a fresh specimen be analysed, and a similar specimen be analysed after a long exposure to the sun and wind. We should like this to be done, and whichever opinion the result sustains we are quite sure Mr. Pearson would rejoice as much as we should; for the object we all have in view is the establishment of truth.—Eds.]

KEEPING THE POLLEN OF AUCUBA JAPONICA.

In answer to "M.," in the Journal of the 25th ult., I remember that at a meeting of the Linnean Society nearly two years ago, it was stated that in order to fertilise the female flowers of Aucuba japonica, cultivators are compelled, from the fact of the male plant flowering earlier, to preserve the pollen in paper, and that pollen so kept, even for twelve or eighteen months, is as efficacious as that recently obtained.—B. Daydon Jackson.

CHEAP PLANT HOUSE.

I have just finished erecting a small greenhouse, and as the construction involves two or three novelties perhaps you may be able to find a corner for this letter, in order to encourage those amateurs who, like myself, have limited means and large desires with respect to horticulture, and who are not afraid of a little hard work in Flora's service. I may preface my account by saying all the work has been done by myself, with the single exception of grooving the rafters—bricklaying, carpentry, glazing, and everything, and I am by vocation none of these trades, and prior to building my house never before laid a hundred bricks in mortar in my life. I have acted on the principle of a fixed roof and sides, and ventilation by means of the four openings in front and the two openings at the back of the roof. The frame of the house serves also the purpose of sash-bars for the glass, so that the wood is economised; and instead of rabbets, and putty, and all that paraphernalia, the rafters are simply grooved about one-eighth of an inch wide and a quarter of an inch deep, and the glass slid into the grooves—not lapped, but simply placed edge to edge, or one sheet butted up against another, as recommended by Mr. Cannell, of Woolwich. As there is naturally a little space left in the groove after the glass is in, I have packed or caulked this from the inside of the house with single strands, in most instances, of tarred string and ratline, and placed caps of wood the whole length of the rafters on the outside. The rafters are dovetailed into the front plate.

Now, as to the roof being watertight, I fancy I hear some of your readers questioning the fact, but I can assure them it is perfectly impervious to any ordinary rain. I do not know what it will be in tornadoes and hurricanes, but my experience up to the present time certainly is that it is perfectly successful. There is more light in the house, it is free from the dirt and grit which always accumulate under laps, and, what is of equal if not greater importance, a broken square can be taken out and replaced in half the time a glazier would take—indeed without calling in the aid of any glazier at all, provided some sheets of the right size are at hand. All that is necessary is to take out the strand of ratline from underneath, and draw the peg or screw in the front plate which prevents the glass sliding down, and the lower panes can then be pushed up in the place of the broken one and a new sheet put in at the bottom, the ratline replaced, and the work is done.

I come now to one of the principal recommendations—its portability. In my position I may have to remove at a short notice, and in that case all that is necessary to be done would be to take out the squares and pack them in the case in which I received them, and the framework of the house will take to pieces like a bedstead. Of course the front brickwork would have to be sacrificed, but then old or new bricks are not difficult to obtain anywhere.

I heat the house by means of a flue. The stokehole is to the right of the door; it takes up but little room, and is ready of access. Instead of the ordinary furnace door and frame I have a plate of iron that slides backwards and forwards. I may say the flue draws admirably, and I have little difficulty in creating any amount of heat. The whole cost of the house, reckoning materials only, the work being done by myself, is under £4 (about £3 10s.), and the dimensions are—outside measurement, 13 feet long, 7 feet 2 inches wide, 7 feet high at back, and 5 feet high in front. I used about three hundred old bricks for the wall, pointed them down, and washed them over with red ochre on the outside, and they look almost as good as new. The size of the glass was 18 inches by 12. I have made provision for the frame containing the glass in the door to swing, if necessary, so as to increase ventilation. I need hardly say this has made an ornamental and substantial house, and well repays the labour and trouble expended on its erection. I would strongly, as an amateur, advise those who, like myself, are enthusiastic lovers of flowers, to procure a house like this, and larger, of course, if their means will permit. It meets the objection often urged, that in case of removal the house would be seriously damaged, if not destroyed; it provides for the ready repair of a broken square; it gives the maximum amount of light—a great desideratum; and if a person only possesses a moderate amount of mechanical knowledge I fear no failure, provided he do not let a few difficulties dishearten him.

I am anxious to have a few climbers, would you kindly recommend me about three with showy flowers and foliage?—A Yorkshire Amateur.

[We can easily believe all you say about the little the glass house has cost you, but then it is not everyone who can turn his hand to carpentering, and bricklaying on his own account. On the principle of the division of labour, it is anything but always the cheapest way of doing things, if the time and labour have to be counted. We know of some cases where mechanics and small tradesmen have had their little places put up, and they found it better to employ a mechanic to work in his overtime, whilst they too worked at their own trade, and thus made the money to pay their neighbours. In many cases that could not be done, and your example then would be worth following. The capping of your sash-bar rafters will be a security against wet, otherwise caps might have been dispensed with, as they will shade considerably. There will be no danger of wet finding its way in between the squares, if at all well cut, but if the squares are at all tight in the grooves there will be danger from expansion. The mode of replacing a broken square is a very good one, as the removing and recaulking will take less time than moving and fixing a square in the usual way. We have objected to grooving when putty was used, as it was so difficult to get it and the bits of glass out. Your plan disposes of such objections. Your air will be quite sufficient, except in very hot days, and then you can open the swing in the door, or the door itself. The portability of your house would have been better secured, if your front had been of wood, and in so many moveable pieces. We are glad you have used a flue, as such a house unheated loses more than half its value.

For climbers we would recommend Mandevilla suaveolens, Tacsonia molliesima, and Passiflora racemosa cærulea.]

BOILERS.

I notice in your columns many allusions to the cost of heating by hot water, when employed in small structures; but I believe that this results from a peculiar fact—that very few people, comparatively, are acquainted with the upright boilers sometimes in use, and where in use, I fancy, deservedly esteemed. I had a small one by Stevenson, with an orna-

mental outer casing of copper, so that it was fitted to stand in an entrance hall, if needed. It was purchased about fourteen years ago, and used to heat my first greenhouse, a wooden shed, with a glazed front and top, about 10 feet by 8 feet, and about 9 feet high at back. Its operations were then extended to a good lean-to greenhouse, with a small forcing or bothouse at one end, the whole about 20 feet long, by about 10 feet wide, and it is still doing its work satisfactorily. In a small greenhouse, if the flow pipe were to be conducted through a tank containing a considerable body of water, a brisk fire for the space of about one hour and a half to two hours, would raise sufficient heat to keep out all frost; and although the little boiler above spoken of does require coke, it does not contain an inordinate quantity, and if the fire be made up at 11 P.M. it might be found still warm at 6 A.M., or even later. It is some years since I worked it, so that I cannot speak positively on minutiæ, but I have three similar boilers on a larger scale now at work, and would be happy to show them to anyone who might wish to see them, as they are most satisfactory.

In all these boilers some heat is wasted in the iron funnel pipe, but then this can be well obviated by leading it into a brick flue, to pass through the house, or to be made use of in heating some other structure. I have done this very successfully with one of mine, and in a larger place it might be made most useful. I am convinced that little boilers combined with a tank arrangement, as a store of heat, and with the patent-jointed pipes, such as Truss's or Riddell's, although more costly at first, are cheaper in the end, when you look at the ease and comfort obtained, and they have the merit of belonging to the tenant, which sometimes is a benefit.—C. M. Major, *Croydon.*

GROWING CELERY IN BEDS.

My attention was drawn to "J. T.'s" observations in page 378, upon growing Celery in beds. I must say I find it a most profitable way of growing it for family use. Were I growing it for exhibition, of course I would prefer the single row; but as I am placed in circumstances much like "J. T.," having but a small space to grow a great quantity, I find the bed system most advantageous. For instance, when I am going to make a trench 6 feet wide, I leave 2 feet at each side to hold the soil taken from the trench, making 10 feet; in this are planted five rows of Celery. Again, when about to plant five single rows, I in general leave from 5 to 6 feet for each row, say five—that is, the five single rows occupy 25 feet. The bed growing the same number of rows occupies 15 feet less, and as we cottage gardeners are looking out for the best way of obtaining a large quantity of produce from a small space, I know of no better than this. I have grown Celery in beds for the last three years, and have had no reason to complain of the bed system. The soil in this garden is light and dry, but I have seen Celery grown with success in beds on heavy soil, though it was well drained.

I will now give a few hints as to how I grow my Celery in beds. I make a trench 6 feet wide, taking out the soil to the depth of 18 inches, dig over the bottom, put in manure, and dig again, mixing the manure well through the soil. I then plant five rows of Celery, and should dry weather set in I give, in the evenings, large supplies of liquid manure or ordinary water. I defer earthing up until the plants are almost full-grown; nor do I tie my plants prior to earthing-up, as I think water is more liable to lodge between the leafstalks when these are tied, often causing decay, and if they are tied tightly they are sure to decay if the crop is not used at once. The heart is not able to push itself up through the tying in order to continue growing, and the consequence is it must die. When I am about to earth-up I take two boards, 6 feet in length and 10 or 12 inches in breadth, place them on edge between the rows of Celery, and earth-in loosely between the boards, lift and place them between the next portion, and so on. I like the soil amongst the plants to be as loose as possible, as the rain passes more speedily to the roots, and the soil dries sooner than when it is otherwise. I leave a little of the hearts above the surface, and by this means I have always done very well with my beds.—Ignorance, *Adamstown.*

FLOWERING DAHLIA IMPERIALIS IN POTS.

Having seen it stated in your Journal that Dahlia imperialis was in flower at Chiswick, is it, may I ask, the first time it has been noticed to flower in England? There has been a plant of it here for two years; it was planted out in a bed in the flower garden in the summer of last year, and grew to a height of 7 feet, showing no sign of flower buds. It was lifted, potted, and placed in a late vinery during the winter. The Vines were started in February, and in March of the present year it produced thirty-six flowers. After flowering it was removed to an orchard house, where it has been ever since, and at the present time shows no sign of flowering.—R. Robins, *Brechin Castle Gardens, Brechin, N.B.*

[Last week a communication stated that the same mode of flowering this Dahlia had succeeded at Waltham Cross. Flowers of Dahlia imperialis were exhibited at one of the Royal Horticultural Society's meetings in December, 1868.—Eds.]

FORCING PLANTS.—No. 4.

Cratægus (Hawthorn).—The Cratæguses are but seldom forced. Nothing, however, is finer, and they force well and easily. The best sorts are the common C. Oxyacantha, C. Oxyacantha multiplex, double white; C. Oxyacantha punicea, scarlet; C. Oxyacantha flore-pleno, double red; and C. Oxyacantha rosea, pink. They are best grown as standards or pyramids, and none but worked plants ought to be employed. They should be kept in the open ground and specially prepared for the purpose. Standards can be most readily obtained with clean straight stems, and they ought to be shifted every autumn, so that they can be had with the roots close to the stem, and not left to grow three or four years without being moved, as in this case the roots are not fibrous except at a distance from the stem, and in taking up we run the risk of the plants growing but little, if at all, in the succeeding year. The plants require no care beyond annual transplanting, and the shortening of irregular growths, until they have formed compact, good-sized heads. I pot them in autumn when the leaves are falling, using pots no larger than sufficient to hold the roots well, but confining rather than overpotting them. Light turfy loam, enriched with one-fourth of leaf soil or old rotten manure, is a suitable compost. Plunge the pots in coal ashes in an open situation, and keep the soil well watered. The potting will act as a check to growth. The plants make short stiff wood, and spurs form plentifully; but if they grow or make shoots more than 6 inches long, I stop them to that length, and in August take the pots out of the ashes and set them on ashes in front of a south wall or other shelter, keeping them well watered until the close of September, and then reduce the watering. The leaves will fall early, and the pots may be plunged to the rim in a sheltered situation, and be taken into the forcing house at intervals of a fortnight or three weeks from December to April.

Pyramids are easily formed; I head-down the plants to 1 foot, and pinch the side shoots at 6 inches, but train the best situated erect as a leader. It is shortened to 15 inches in autumn, and the plant lifted, and this is continued until I have plants large enough, when it is potted, and grown a year in pots as described for the standards. They may be had of any size from a tiny tree a yard or less high, up to that of a giant, and if the close-stopping system be practised, they need not be of greater diameter than twice that of the pot.

The Thorns force as easily as Lilacs, are fully as sweet, and far more handsome. I think it would be easy to have May blossom at Christmas. The plants, after forcing, should be continued under glass, be hardened-off, and then placed outside. Some may be forced again the second year, but they are all the better of a year's rest, pinching off the blossoms as they appear, so as not to weaken the plants needlessly. The older they are the better they flower. Top-dress in autumn with rich loam and old cow dung, removing the old soil to some extent from around the sides of the pot. The results will be seen in the bloom, and there is no fear of the fruit falling.

The New Scarlet Thorn is a splendid variety. It will bloom in 6-inch pots.

The temperature required for forcing is the same as for Lilacs.

Cytisus (Laburnum).—The Scotch (C. alpinus), is the best for forcing and every purpose. Plants should be grafted; they seem to flower at an earlier age without running so much to wood. Pyramids or bushes may be formed like Apple and Pear trees, and standards have a fine effect, for the flowers, being seen from beneath, appear much larger than when on the level of the eye, or below it. The treatment is the same as that of the Thorns. The older the plants are the better, and

you cannot restrain them from blooming, only keep the roots confined. They form spurs very closely, and with stopping the shoots bloom at almost every joint, but stopping need only be practised to secure shoots where wanted and good form. Lifting annually or biennially, will cluster the pot plants with flower buds. They may be kept for years in pots, forcing every second year, though for very early bloom the most promising of those forced in the previous year may be forced a second time in succession.

Philadelphus coronarius.—The Syringa, or Mock Orange, requires the same treatment as the Lilacs, both as regards the preparation and forcing of the plants. The scent of the flowers is so powerful, that the air is made rather oppressive by it when a number of plants are grown. One, or at most two, will be sufficient to have in flower at one time in a house; but it should be noted the scent is not so powerful in the flowers of the forced plants as in those in the shrubberies. Small plants, if removed frequently, and grown a year in pots as described for the Thorn and Laburnum, bloom well.

Ribes sanguineum, and its varieties album and atrorubrum, respectively with red, white, and deep red flowers, are well-known early-flowering plants of no mean beauty, and though common are not so generally forced as they deserve to be. A well-grown bush of any of the varieties named is a fine object when in full bloom in January, and so is a standard with a straight clean stem, and a round head clustered with pretty drooping flowers, when placed on a dinner-table in midwinter. An 18-inch stem is quite high enough for that purpose, and for greenhouses and conservatories any height from 18 inches up to 6 feet will do. The best plants for tall stems are seedlings. They grow more freely than cuttings or layers, and form straighter stems, and more quickly. Besides, they seldom give any trouble. There is the labour of grafting at the height required, and then we proceed to train the head in the form of an umbrella, and when a good head is obtained take up and grow the plants a year in pots, treating them in the same manner as described for the Thorns. If one has not worked plants, all he has to do is to select plants with clean straight stems, and train them upright to a stake, removing all side shoots as they appear, and when the desired length of stem has been attained, head them over, removing all the eyes but three of the highest up. These produce shoots in the following spring, the pruning or heading-back being done in autumn, and whilst the shoots are young and pliant bend them down gently, bringing them to a horizontal position by means of strips of matting, taking care to dispose them equally all round. When they have grown 6 inches pinch out their points, and the shoots which they afterwards make must be tied down so as to give an equal growth on all sides. If the second growths do not push more than 3 or 4 inches, let them alone; but if they exceed that length pinch them back to that. Do not lift them in autumn, nor use a knife, except to cut off any ill-placed shoot. In the following year all that is needed is to train down the lowest shoots and stop those disposed to grow irregularly, and all of the shoots when they have made others 6 inches long, thinning them out where they cross each other, so as to form a compact, symmetrical head. Lift and pot in autumn. I then plunge the pots in coal ashes in an open situation, and water freely throughout the summer, placing the plants in a warm situation in August, and giving no more water than enough to keep them from flagging. The leaves fall early, and the plants are fit for forcing by November, and in point of temperature succeed under the same conditions as the Deutzia gracilis. The stems may be feathered by leaving one joint or leaf on the side shoots, and a spur will probably be the result; if not, again pinch the shoot coming from it to one leaf. The stem will be clustered with spurs, and when in flower will have a good effect, especially when surmounted by a well-bloomed head.

Pyramids are formed in the same manner as in the case of the Thorn, only as the shoots are disposed to grow erect, we must tie them down before they become too stiff, stopping them when 6 inches long; and the side shoots produced, when not required to fill vacancies, should be pinched off at the leaf next the shoot from which they spring. Neat plants may be had in two or three years, and when grown a year in pots are very pretty. They may be taken up from the open ground, potted, and forced at once, but there is no comparison between them and those which have been established a year in pots. Sandy loam, with a little leaf soil, is the most suitable compost.

Jasminum officinale (White Sweet Jasmine).—This should be grafted on stems 18 to 24 inches high, and the erect shoots trained downwards, but all growing more than 9 inches long should have their points pinched out; and in spring, before they begin to grow, thin out the shoots where too close together, especially those which are the weak and crowded. Neat plants may be formed in 6-inch pots, and these after the second year are fit for forcing. Larger plants may be grown in larger pots. The plants ought to be grown constantly in pots in a warm situation, and towards September should be placed on coal ashes in front of a south wall or fence, and no more water given than enough to keep the foliage fresh. They ought to be wintered in a cold pit, or under a south wall, the pots being plunged over the rim in coal ashes. Plants of the proper size for forcing should have the wood well ripened by being placed in a warm position in August, or early in September, reducing the water given as much as possible, and placing them in a cool dry house in October, where they should be kept dry, but not so much so as to cause the wood to shrivel. Forcing may be commenced in December. The temperature and treatment are the same as for Spiræas.

Jasminum officinale grandiflorum is better than the old kind, and blooms very freely when grafted on the common Sweet Jasmine; indeed, both kinds ought to be grafted, otherwise they make too long shoots, but the grafting appears to check the flow of sap, and tends to produce a more shrubby habit.

Jasminum nudiflorum on stems a yard high has a fine effect when the shoots hang down to the rim of the pot, and are covered with a mass of bright yellow flowers. In a cool house it blooms at Christmas, and during January. No forcing is required.—G. Abbey.

ENTOMOLOGICAL SOCIETY'S MEETING.

The first meeting of the present season was held on the 1st of November at Burlington House, Mr. H. W. Bates, President, being in the chair. Fifteen new members were proposed for election, and a large series of donations to the Society's library announced, including the publications of the Linnean and Zoological Societies of London, and of numerous Natural History and Entomological Societies of Europe and America. Two new parts of the Transactions of the Society were announced as having been published since the last meeting.

Mr. Ianson, on behalf of Dr. Power, exhibited eight new species of Beetles new to the British list, including four species of Bruchus, Triarthron Maerckelii, captured at Esher in July and at Shirley in August; also Phratora cavifrons from Esher, Cowley, and Darenth, and species of Niptus and Silvanus. Mr. Grut exhibited various new Beetles from Trebizond captured by M. Deyrolle, including four new species of Carabus. Mr. McLachlan exhibited a series of specimens illustrating the transformations of Mantispa pagana received from Dr. Brauer, of Vienna, who has discovered that this species is parasitic in the nest (or rather egg-ball) of a Spider of the genus Lycosa. In the full-grown larva state the feet are nearly obliterated; the pupa closely resembles that of Hemerobius, and is enclosed in a silken cocoon. Mr. Ward, of Halifax, sent for exhibition some very fine and interesting species of exotic Butterflies, including the gigantic Papilio antimachus, captured about two hundred miles east of Old Calabar; the only example hitherto known of this species was captured by Smeathmann, and figured by Drury and Donovan, and is now in the collection of the late Mr. W. S. MacLeay in Australia, having been purchased by him at the sale of Drury's collection. The female of the very beautiful Ornithopterus Brookeanus, of which only males from Borneo had hitherto been obtained, was also exhibited; likewise P. zalmoxis, received by Mr. Cutler from the Cameroons, and several fine species of Charaxes.

Mr. F. Smith exhibited specimens of the rare Meloë rugosus captured in the middle of October, crawling among grass in the neighbourhood of a colony of wild bees of the genus Anthophora, in which they were supposed to be parasitic, near Southend, Essex. They are extremely pugnacious, and of twenty-five specimens captured and kept alive only four remained perfect, the others having fought and lost portions of their legs and antennæ. Mr. Albert Müller exhibited an interesting collection of galls found upon various species of vegetables, including two kinds of excrescences on the stalk of the Maple leaf, one formed by a dipterous insect, and the other being solid and thorn-like, and supposed to be produced by the punctures of Acarus Aceris, which ordinarily forms Pear-shaped red galls on the leaves of the Maple. It was stated that the extensive series of galls formed by the late Mr. Armitage is now in the museum of the Philosophical Society of Leeds.

Mr. Wormald exhibited some species of Butterflies from Shanghai, and Mr. Dunning some Moths from the same place, reared by Mr. Holdsworth from the same batch of larvæ. The Moths appeared, however, to be identical with specimens named by Mr. Walker in the British Museum Œona punctata, Lasiocampa remota, and Lebeda hebes!

Professor Westwood communicated a letter received from Professor Stal, of Stockholm, containing an account of all the typical collections of insects in the museums of Stockholm, Upsal, and Lund, including

those of De Geer, Queen Louisa, Payknll, Gyllenhal, Schonherr, &c. Letters were also read from M. Done and Dr. Kraatz.

A memoir by Mr. Kirby was also read, containing notices of the species of Butterflies introduced and named by Gmelin in his edition of the "Systema Naturæ" from the Museum Leskeanum, in which they had been described by Schach, and of which the types are now preserved in the museum of Dublin. The President exhibited a drawing made by Mr. Burchall in New Grenada, representing the caterpillar of one of the Sphingidæ, regarded with great dread by the natives as a small and poisonous kind of snake, the resemblance being caused by two large eye-shaped spots on the retractile neck of the caterpillar.

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

Mormodes Greenii (Mr. Charles Green's Mormodes). *Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria.—Probably a native of Mexico. Flowers yellow, spotted with scarlet, and powerfully aromatic.—(*Bot. Mag.*, *t.* 5802.)

Vellozia elegans (Natal Vellozia). *Nat. ord.*, Velloziaceæ. *Linn.*, Hexandria Monogynia.—Native of the Cape of Good Hope. Flowers white.—(*Ibid.*, *t.* 5803.)

Calochortus uniflorus (Single-flowered Calochortus). *Nat. ord.*, Liliaceæ. *Linn.*, Hexandria Monogynia.—Native of the high plains of Santa Cruz. Notwithstanding the name, the flowers are usually more than two. They are pale rose-coloured. —(*Ibid.*, *t.* 5804.)

Rhodotypus kerrioides (Japanese Rhodotypus). *Nat. ord.*, Rosaceæ. *Linn.*, Icosandria Digynia.—"A very elegant shrub, native of Japan, and, no doubt, hardy." Flowers white; fruit like a Blackberry.—(*Ibid.*, *t.* 5805.)

Iris nudicaulis (Naked-scaped Iris). *Nat. ord.*, Iridaceæ. *Linn.*, Triandria Trigynia.—Native of Bohemia, Silesia, &c. Flowers dark purple, veined darker, base white.—(*Ibid.*, *t.* 5806.)

Apple Annie Elizabeth.—"Awarded a first-class certificate by the Royal Horticultural Society's Fruit Committee, on the 6th of October, 1868,—such is our authority for recording that the variety merits the attention of the pomologist. We have to thank the raisers, Messrs. Harrison & Son, of Leicester, by whom it is being distributed, for the specimens.

"We learn from the Messrs. Harrison that the examples hitherto exhibited of this valuable culinary Apple have been obtained from the seedling plant, which has been once transplanted, so that doubtless it will be seen much finer when obtained from trees properly worked and cultivated. Its pedigree cannot be exactly ascertained, but it is believed to have been obtained from the Bess Pool. The tree is of upright or pyramidal habit, compact, and remarkably sturdy, the bark smooth, bright, and mottled, and the leaves often acquiring very large dimensions. It is, moreover, an excellent cropper, and the fruit is generally of large size, round in its outline, but widest at the base, prominently ribbed or angular, especially towards the eye, which is large, and deeply set in an irregular angular basin; the skin is pale yellow, suffused and somewhat splashed with crimson on the sunny side; stalk short, deeply set. The flesh is white, firm, but crisp and tender, with a fine brisk flavour. It is commendable for its late-keeping properties, the ordinary season for use being from December to June. Specimens gathered in October have been kept good till the following October, twelve months after being gathered, so that we may fairly state that it is an excellent late kitchen Apple, and we learn that when kept till spring is of very good quality for dessert. By the month of April it acquires a more decided yellow colour, with much brighter crimson markings than is shown in our figure, which gives the appearance of the fruit at the time it comes into use."—(*Florist and Pomologist*, N.S., ii., 241.)

ON THE LEAVES OF CONIFERÆ.

Botanists can scarcely have overlooked the fact that the true leaves of Pinus consist of bud scales; and that what are known as leaves, and what Dr. Engelman ("Gray's Manual," fifth edition, page 469), calls "secondary leaves," are but phylloid shoots, but I have failed to find any specific reference to the fact in botanical works. Dr. Dickson, however, in a paper on the phylloid shoots of Sciadopitys verticillata ("Proceedings of Botanical Congress," 1866, page 124), remarks, "In Sciadopitys I have to call attention to the fact that the leaves of the growing shoots consist, as in Pinus, entirely of bud scales." One would suppose from this incidental reference to Pinus that he was acquainted with the fact that the so-called leaves of Pinus were phylloid shoots; but as the object of the paper is to show that the so-called leaves of Sciadopitys are not true leaves, and as anyone must know that they are not, if already cognisant of the fact in Pinus, we may take it for granted that at any rate if not entirely overlooked, little thought has been given it. I believe I am occupying an entirely original field in pointing out the true nature of leaves in Coniferæ, and that the increased knowledge will have an important bearing on many obscure points in their study.

Dr. Dickson uses but the language of general botany when he describes the true leaves of Pinus as "bud scales," meaning thereby the scaly free portion just under the "secondary leaves," of Engelman, and sometimes forming sheaths around them. But these free scales are scarcely leaves. The chief portion of the true leaves in most plants of the order are adnate with the stem. Sometimes they have the power to develope into scaly points, at others into foliaceous tips, and at other times without any power but to preserve their true leaf-like character. Larix affords the best illustration. The true leaves are linear spathulate, entirely adnate to the stem. There are two kinds of stem-growth on Larix. In one case the axis elongates and forms shoots; in the other axial development is arrested, and spurs are formed. On the elongated shoots the leaves are scattered; on the spurs they are arranged in whorls. The power of elongation possessed by the shoot is imparted to the leaves which are adherent to it, and they produce green foliaceous awl-like tips. The power of elongation which the spurs have lost is also measurably lost to their leaves. They develope themselves fully, although they have no stem to adhere to; they preserve their spathulate form, but cannot produce the awl-shaped tips of the shoot leaves. There are, therefore, two forms of leaves on the Larch, the one free, the other adherent; and we have a novel principle very clearly illustrated, that *strong axial development* (vigour) *is a characteristic of adhesion, while the reverse* (weakness) *is characterised by a free system of foliation.* Any species of Larix will sustain this observation, and L. leptolepis, as a vigorous grower, is the best.

The characteristics of the foliage described in Larix may be found in a greater or less degree in a great many species of coniferous plants. In Cryptomeria the leaves adhere for four-fifths of their length on vigorous shoots; but on the more delicate ones they are free for three-fourths or more. In Juniperus the different forms of foliage are well known, especially in J. virginiana, J. chinensis, and J. communis. On the vigorous shoots adhesion takes place for nearly the full length of the leaves, but on weaker ones the leaves are very nearly free. In Thuja, Biota, Retinospora, Cupressus, Thujopsis, indeed most of the section Cupressineæ, these variable degrees of adhesion may be found, and always in relation to the absence or presence of vigour; and on this question of vigour it will be well here to make a few remarks. The power to branch, I take to be a high mark of vigour. The young seedlings of most coniferous trees grow but a few inches the first year and have no power to branch. The power increases with age, and in all cases in proportion to the vigour of the plants. In Thuja, for instance, no branches appear till the second year. They increase in number, until, when in its prime, branches appear from every alternate pair of axils, and, as these are decussate, this gives the fan-like form of growth of which the Arbor Vitæ affords a familiar illustration.

This varying power of adhesion in the true leaves, and in connection with vigour, enables us to explain many matters hitherto not understood. For instance, Dr. Lindley describes a form of Biota as B. meldensis, suggesting that from its appearance it must be a hybrid between the Red Cedar and Chinese Arbor Vitæ. It is but B. orientalis with the leaves moderately united. Thuja ericoides of gardens was long supposed to be a Japanese species; it is but an entirely free-leaved form of Thuja occidentalis. Retinospora ericoides of Zuccarini is but a free-leaved form of some Japanese plant; and in all probability many species of Retinospora so marked in herbaria, are all forms of one thing with more or less adnated leaves. In all these cases delicacy of growth and freedom of leaves go gradually together, as before indicated.

One of the most remarkable instances of the value of this principle however, will, I have no doubt, be in fixing the identity of the Japanese genus Glyptostrobus* of Endlicher, with the

* It was the intention of the author to refer his remarks on Glyptostrobus to G. sinensis, *Endl.*

American Taxodium of Richard. In a shoot 1 foot in length of the latter we find perhaps four or six branchlets; in the same space in Glyptostrobus we shall find a score or more. Indeed, in this plant, a branchlet springs from nearly every axil on the main branch, showing an extraordinary vigour. As vigour is opposed to a free development of foliage, the small thread-like leaves of Glyptostrobus are naturally to be expected, and the free leaves distichously arranged are the natural concomitant of the weaker Taxodium. Fortunately, I am able to sustain this theory by actual facts. I have a seedling tree ten years old of remarkable vigour. It does not branch quite so much as the typical Glyptostrobus, but much more freely than any Taxodium. The result is the foliage is aciculate, not distichous, and just intermediate between the two supposed genera. But to help me still more, my tree of Glyptostrobus has pushed forth some weak shoots with foliage identical in every respect with the intermediate Taxodium. Specimens of all these are presented with this. In establishing Glyptostrobus, Endlicher notes some trifling differences in the scales of the cones between it and Taxodium, but all familiar with numerous individuals of some species of Coniferæ, Biota orientalis for instance, know how these vary. There can be no doubt, I think, of the identity of the two; and this will form another very interesting link in the chain of evidence, that the flora of Japan is closely allied to that of the United States.

If we were to look on the so-called leaves of Pinus and Sciadopitys as true leaves, we should find serious opposition to my theory that a vigorous axial growth is opposed to the development of free leaves in Coniferæ, for we should see a class of plants which notoriously adds but from three to six branches annually to each axis, clothed with foliage. But admitting them to be phylloid shoots, it confirms our theory in a strong degree. We then see a plant loaded with branchlets, and so great is the tendency to use them instead of leaves, that in some cases, as in Pinus Strobus, P. excelsa, and others of a softer class of Phylloideæ, the bud scales are almost entirely confined to the sheathing leaflets; just as in the very rugged, hard leaved, almost spinescent forms, like Pinus austriaca, we find them more dependent on well-developed adnate leaf scales. In Abies of old authors, A. excelsa for instance, we have a numerous branching tendency; hence we have true leaves though partially adnate, and no necessity for phylloid branchlets. In Picea of Link, almost near Abies, taking P. balsamea as a type, we have a rather weaker development, slower-growing and less hardy trees, and the leaves are nearly free. Could some of the shoots of Abies be arrested in their axial development as in Larix, we should have the remainder increased in length, and the fewer branchlets, and two forms of leaves, just as in Larix. Should on the other hand, the plant increase in vigour, there would be no class of free leaves; adnation would be the law, and metamorphosed branchlets prevail. Starting from Abies, extra vigour makes the Pine, extra delicacy the Larch. It is the centre of two extremes.

That the fascicles in Pinus are phylloid shoots I think cannot be questioned. Their position in the axils of the true leaves, as beautifully shown in Pinus austriaca, indicates the probability. Their permanency in proportion to their induracy is also another point. The soft ones of the Strobus section retain vitality little longer than some true leaves, while the spinescent ones of P. austriaca remain green for four or five years. But the strongest of all points is that on dissection of an old fascicle it will be found to have a distinct connection with the woody system of the tree, and that these minute woody axillæ under each fascicle increase in size with the age of the sheath. With a very little encouragement these woody axillæ can be induced to elongate and become real branchlets. If the leading shoot, for instance, of a Pine be tipped in May just after pushing, bulblets will form in every fascicle below, and the next season the bulblets will produce weak branchlets, although this might be said of true leaves, which are supposed to bear an embryo shoot in the axil of every one. So much stress need not be put on this fact, as the others are sufficient. It is introduced, and its weak nature commented on, as it furnishes the chief point in Dr. Dickson's argument for Sciadopitys, which amounts to little more than that the apparently single phylla is really a double one—a two-leaved fascicle united by a transformed sheath through its whole length. Carrière has since pushed Dr. Dickson's observations farther by noting in the "Revue Horticole" really bifid leaves, with little verticils in the axils (see reference in *Gardeners' Chronicle*, May 2nd, 1868), an observation which I confirm by a specimen exhibited herewith; yet as I have said, it is by itself not wholly free from the objection that it may be but a modified form of regular bud growth; but together with my other observations I think they do serve to confirm the point of these so-called leaves being but phylloidæ.

In conclusion I will restate the main points of this paper:

The true leaves of Coniferæ are usually adnate with the branches.

Adnation is in proportion to vigour in the genus, species, or in the individuals of the same species, or branches of the same individual.

Many so-called distinct species of Coniferæ are the same, but in various states of adnation.—Thomas Meehan (*From advance sheets of Proceedings of American Association for Advancement of Science at Chicago*, 1868, quoted in *American Gardeners' Monthly*.)

NOTES AND GLEANINGS.

The King of the Belgians visited the Kensington garden of the Royal Horticultural Society last Saturday. He was received by some of the Vice-Presidents and members of the Council, and in the conservatory about two hundred ladies and gentlemen were assembled, notwithstanding the inclemency of the day. Messrs. Veitch, Messrs. Arthur Henderson & Co., Messrs. Lee, Mr. Williams, Mr. Turner, Mr. Wimsett, Messrs. E. G. Henderson & Son, and Messrs. Salter exhibited some beautiful groups of flowers; and Mr. Fox had an extensive display of garden vases, ornaments, tiles, &c. A new Hippeastrum was named "Leopold" by the King, at the request of Messrs. Veitch.

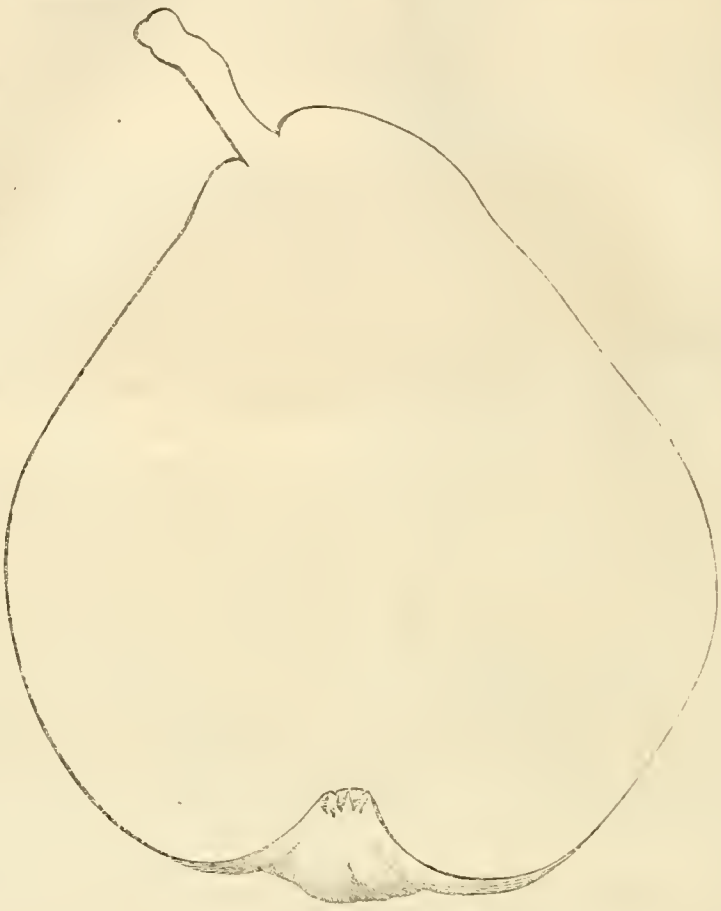
THE DECLINE OF FRUITS IN AMERICA.

One of the great difficulties we have to encounter is the deterioration of varieties. However we may theorise in regard to this matter, it must be admitted, from the practical point of view, that some fruits have so declined as to render it absolutely necessary to replace them with new varieties. And what has been true in the past will be so in the future. Witness certain kinds of Pears in our own day—the St. Germain, Crassane, Brown Beurré, White Doyenné, and others once so excellent; where are they now? Some of them are occasionally to be seen on the virgin soils of the West and South; yet for the great majority of locations they will continue to be worthless. And even on these new soils, where they now flourish in their pristine excellence, we have reason, judging of their future from the past, to anticipate that no long time will elapse before this decline will reach these now favoured regions. Within less than a generation the Pears alluded to flourished throughout western New York, as well as, in their early history, on the propitious soil of France. And even among the more modern Pears we notice—as, for instance, in the Beurré Diel and Flemish Beauty—signs of the same decay. And so with the Grape. Where the Catawba and Isabella Grapes once succeeded perfectly, they seem now to be failing, and in many sections of our country are no more to be relied on. Even the Concord, now so popular, indicates that in time it may follow in the same degenerate strain. While we indulge in these forebodings we cannot but express the deep regret we feel for the loss of such fine fruits. Other fine fruits are following in the same course. This should not discourage us, but rather increase our enterprise for the production of new sorts to keep up the deterioration which seems incident to cultivation. We have to learn not only what varieties succeed in certain districts, but throughout the country. Already we have ascertained that some kinds flourish throughout a wide range of territory. For instance, the Red Astrachan Apple and Bartlett Pear seem to prosper everywhere. When we reflect on the wide expanse of territory daily becoming susceptible of cultivation, and that our fruits must ultimately be spread over these vast fields, it becomes a matter of great importance to increase our native fruits, some of which may be suited to these regions, and thus replace those which may decline. We, therefore, give a hearty welcome to the efforts of all who are labouring in this praiseworthy cause. Who can estimate the importance and value of a new variety of fruit, which shall be adapted to the wide range of our rapidly extending cultivation? He who shall originate a new Apple, Pear, or Grape, which shall be worthy of being handed down to posterity, should be held in remembrance as a benefactor of mankind. He who shall discover a remedy for the Pear blight and other diseases incident to vegetation, which now

affect our trees, or an easy method for the destruction of the horde of insects so alarmingly injurious to our fruit crops, shall have his name transmitted to future time as second only to those who discover methods for the alleviation and cure of diseases which affect the human system.—Marshall P. Wilder (*Boston Cultivator*).

DOYENNÉ DU COMICE PEAR.

The specimen we have here figured was one we received from Mr. Rivers, of Sawbridgeworth, and which was from a tree grown in a 10-inch pot. It weighed 1 lb., and its flavour was as rich as this excellent variety usually is. Mr. Rivers says, "This Pear, unlike many others, ripens kindly under glass, and preserves its full flavour. In the hot summer of 1868 some trees in pots in an orchard house were full of fine fruit; others had a rosy cheek, ripened on the trees, and were quite exquisite."



It is now some years since this fine Pear was first brought to the notice of the Pomological Society at one of its meetings in St. James's Hall. Since that time it has made its way, but slowly, into cultivation, and it is remarkable that it should be so, for we never recollect, among all the specimens of the fruit we have ever seen, having met with one which was not of the greatest excellence. A correspondent says, "As to Pears, Doyenné du Comice is emperor among them; nothing (save Knight's Monarch), is worthy for him even to tread upon—at least of his contemporaries. I could eat him all day long, and begin again at sunset."

Our figure is one of a specimen of unusual size, the average being from three inches and a quarter to three inches and a half long, and two and a half to two and three-quarters wide. The form is long obovate, and often somewhat turbinate. The skin is lemon yellow, speckled all over with pale brown russet, which in some parts is so thick as to form irregular russet patches, and particularly so towards the eye and the stalk; on the side fully exposed to the sun there is a pale rosy cheek. Eye small, half open, with short pointed segments. Stalk an inch long, stout, fleshy at the insertion, and set in a rather deep and narrow basin. Flesh white, buttery, tender, melting, rich, sugary, and delicately perfumed. It is ripe in the beginning and throughout November; but if gathered early it will keep much longer.

This is not only a fine Pear, but by far the finest and most excellent of all our numerous November varieties. The tree grows freely on the Quince, forms a very handsome pyramid, and bears when quite young, but never so abundantly as to require thinning, like some varieties.

This valuable Pear was raised in the fruit garden of the Comice Horticole of Maine-et-Loire, at Angers, and first fruited in 1849.

GROUND VINERIES, CLOCHES, AND RENDLE'S PROTECTORS.

PEACHES AND NECTARINES AS CORDONS.

In page 349, "R. F." expresses his want of experience in the cultivation of these trees as cordons in ground vineries. As I am proud of mine, allow me to give an account of them. It is now three years since I planted in my ground vinery two double cordons, one Peach and one Nectarine tree. The latter has grown more vigorously than the former, and is now 24 feet long, each arm measuring 12 feet; it is a beautiful tree, and full of blooming spurs. This condition has been brought about by incessant summer-pinching to two and three leaves.

This tree is in the centre of a ground vinery 3 feet 6 inches wide, the south side of which opens, not with hinges, but swings on two bolts, one end of which is a screw, which is screwed into the end bar; and that part of the bolt on which the side swings is let into the frame, and is smooth. I enclose a sketch of this much-improved ground vinery. The dotted lines at each end show the position of the bolts on which the light swings, and thus there is a perfect command over the cordon or Vine inside. A small handle is fixed on the bottom bar. This improvement adds but little to the cost; for frames 7 feet long and 3½ feet wide I have paid 10*s.* each, to which must be added 12*s.* for painting and glass, thus giving an area of about 22 feet of cultivable space for cordon trees, Vines and Strawberries or Lettuces.

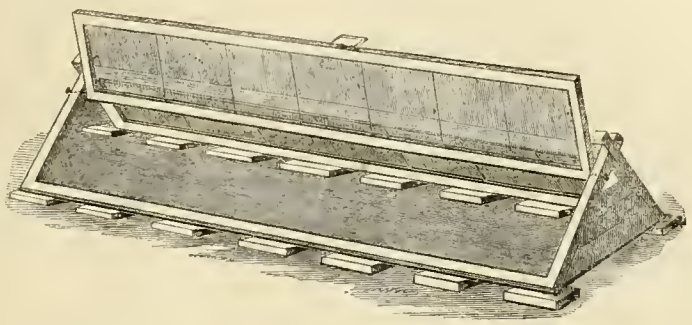
"R. F." says that they, "the ground vineries are dear enough, and that they are huge moveable glasses." I should like to show him mine, for he has evidently not seen their improved state.

The question now arises, Are they more convenient than cloches, which poor Loudon years ago in vain endeavoured to introduce, the duty on glass quite precluding their being made in England? They are now, however, manufactured at a cost of 1*s.* 6*d.* each, and are sold rather extensively to those who are not experienced in horticultural economy, which, like political economy, is not a light study.

If I remember correctly, each cloche 16 inches in diameter, being bell-shaped, gives a circle only 14 inches in diameter—153 square inches of cultivable area, or about 1 square foot. It will thus take twenty cloches to give us 20 square feet, in which to winter Lettuces, &c. Let us now compare the cloche with the improved ground vinery. The cloche can only be used for Lettuces and other winter salad plants, and requires much lifting and trouble. The improved ground vinery, with

one side in a wooden frame swinging on bolts, is equally eligible for the same purposes. The cloche is very liable to breakage, the thick coat of litter required to protect it in winter becoming matted with frost and snow, and often making the footsteps of the workman uncertain, so as to bring on a dangerous stumble. The improved ground vinery may be covered with frigi domo, felt, or double and treble small mats, so as to be perfectly frostproof, without the slovenly litter of a French kitchen garden.

My double-cordon Peaches, Pears, and Apricots occupy the centre of my improved ground vinery. This single row of cordons in the centre leaves a valuable space on each side in which, during the winter and early spring, fine Lettuces may be gathered, or two rows of Strawberries in pots may be partially plunged, so as to give a good early crop before the cordon trees are in full growth. The side swinging on bolts, gives an easy access to all that is grown in these nice structures without moving them, or as is the case with cloches, lifting them off to attend to the plants under their cover.



To make my statement clear, we must revert to the comparative cost of cloches and ground vineries. I have stated above that twenty cloches would be required to give, in round numbers, 20 square feet of cultivable space, the cost of which would be 30*s*. The cost of a 7-feet improved ground vinery, 3½ feet wide, may be estimated at from 22*s*. 6*d*. to 24*s*. In this is a most convenient cultivable space of 21 square feet, and in this space from six to seven rows of winter Lettuces may be grown, as they do not require to be so thinly planted as summer Lettuces. We thus have at a less cost a greater number of plants more easily protected, and easily comeatable, without lifting and without litter. I have taken Lettuces as they are the great boast of those who write about cloches, merely to show that even with them the improved ground vinery is a forward step, leaving out the great advantage of a combined culture—cordon trees or Vines in the summer, and Lettuces and Strawberries in winter and spring.

Our other rival to the cloche is Rendle's plant-protector formed with common kiln bricks,* and a row of grooved bricks, in which is slipped the glass, placed on them. The most eligible width for this most useful and durable structure is 2 feet; a 7-feet length, with 21-oz. glass, fourths, costs about two-thirds the price of the same length of the improved ground vinery. For Lettuces or salads three courses of common bricks at the back may be used, and two courses in front, and on them a row of grooved bricks. No mortar, paint, or putty is required, so that a length of 50 feet may be erected in little more than two hours. For Vines or cordon trees five courses of common bricks are required for the back, and three courses for the front, but the addition of a course of bricks is the work of a very short time. The cultivable space in the plant-protector is less than that of the improved ground vinery, but as its walls are perpendicular every inch may be used. In winter the walls may be closed; in spring and summer air may be admitted by shifting the common bricks so as to form "pigeon holes" in both walls.

The plant-protector may thus be made a warm shelter in the winter, for not only salads, but bedding plants, and may be made frostproof with coarse woollen coverings. It will thus be seen that this second rival to the cloche has many advantages, for instead of a thin bell-shaped covering of glass, very cold at night, and very hot by day, the bricks retain and give out heat so as to neutralise the effect of slight frosts, besides which, without the employment of long stable manure—so offensive in French gardens and so untidy, winter coverings for the protectors and the improved ground vineries will one day be manufactured of shoddy or some other cheap woollen material. In ten years or so the few cloches left in this country after our freezing and thawing cloudy winters, will be looked upon as relics of a bygone age, for English gardeners are now on the alert, and much will yet be done to help our untoward climate. We shall, doubtless, yet have inventions that will put us to the blush when we think of the bell-glasses of French gardens having been recommended to English gardeners.—Vitis-Sator.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Those who are desirous of laying the foundation for a good garden in the ensuing year, should now closely review the routine of cropping for the past summer, and even that of the preceding year. Various rotations are practised by gardeners, many of them being based on no better foundation than the convenience of the hour; but when the kitchen garden is sufficiently extensive, and where much produce is required, the rotation of crops should be carefully studied. An opportunity will now occur of covering the roots of *Asparagus* with a good coat of the best rotten manure. Hard frosts frequently do serious injury to the roots, owing to the want of such protection. Celery ground will answer well for a new plantation; it should be ridged to mellow as the stocks are taken up. The great difficulty is to procure fresh ground for the Cabbage tribe, so numerous are the kinds, as well as successions, in cultivation. Broken-up plantations of Strawberries, Raspberries, and other bush fruit, with Celery ground, should at all times be set apart for some of the Cabbage tribe. The ground in which Celery has been grown, especially in the Scotch or bed fashion, is also suitable for new Asparagus beds. Potatoes prepare ground well for almost any crop. Deep or tap-rooted crops should be succeeded by shallow or fibrous-rooted ones. Carrots and Onions in rich kitchen gardens, will be found a much safer crop if grown on high-raised beds without any manure. The best policy with *Lettuces* intended for the supply next spring, is to allow them to freeze tolerably firm before covering them up. A very light screen of straw should be shaken over them at first, and when this is frozen add a little more, the object being to keep them frozen as long as possible. Above all, do not uncover them when a thaw arrives; let them remain until completely thawed. When the course of cropping has been decided upon for the ensuing year, and duly entered with numbers in the garden book, the usual practice is to set up laths opposite to the space appropriated for each crop, with a number corresponding with the book, and the name of the crop on one side, and on the other the name of the manure, if any, and its quantity, with the mode of cultivation—digging or trenching. This done, a labourer who can read the label can set out or proceed with the work at any spare time. This, therefore, is a matter which should receive attention. As severe weather may be expected, everyone possessing a garden should, as far as possible, protect anything tender.

FRUIT GARDEN.

In all cases in which the leaves have fallen, proceed with pruning and nailing. See that standard trees which have been recently moved or root-pruned are firmly secured against winds; also finish any root-pruning or transplanting remaining to be done.

FLOWER GARDEN.

In most gardens leaves can be collected, and when properly managed they form, perhaps, the most useful source of bottom heat with which we are acquainted, except, of course, hot water. If not already done, the leaves necessary for carrying on the business of the ensuing year should be collected as early as possible, and laid close together to heat. After fermenting for three weeks or a month, they will be in excellent order for use; in this state they will both heat with more certainty and

* Kiln bricks are more regular in their shape than stock bricks.

tread more closely. In order to be ready to make up propagating-beds of all kinds, or to form linings, it is necessary to have in the course of next month a mixture composed of hot dung and leaves; therefore, before it is to be put up into a bed, a quantity of hot dung should be drawn from the stable-yard to the leaf yard, thrown together, and well watered, in order to allow the fiery heat to escape. When fermented thus for a week or so, the manure may be mixed with leaves. About four parts of leaves to one of hot manure, will make an enduring mixture. This provided, a good hotbed can be made up at any time, for if the dung has had one heating previous to its mixture with the leaves, little danger need be apprehended from impure vapours, provided the most ordinary precautions be observed. The chief anxiety of the amateur, as far as Tulips, Dahlias, Carnations, Pinks, &c., are concerned, is now at an end. Tulips ought all to be planted, and if the bed has been properly made will require but little attention till they are fairly out of the ground. Dahlias ought all to be out of the ground by this time, and their tops cut off; and having been exposed under cover in a dry airy place, they will be ready to be stored. Carnations must be kept hardy—that is to say, if they have been potted early; if obtained since the middle of October they will require much more attention, for at this time being comparative stationary, it will be found that late-potted layers are more susceptible of damp and frost than those which are well established. Take the first opportunity of carefully looking over Carnation layers that are in frames; it is possible that dirt may have settled in the axils of the leaves; as this retains moisture in a very inconvenient degree, it is highly necessary for the health of the plants that it should be removed. Modes of storing half-hardy plants vary in different situations; some persons can afford pits, some even can spare house room, and some are driven to the cellar. Whatever mode be adopted, let it be borne in mind that confined damp is nearly as prejudicial as frost. A lean-to shed is a very good place, and plants with a ball of earth dried on them, will keep very well here plunged in coal ashes, with the addition of an old mat and a little straw over the shed during severe weather.

GREENHOUSE AND CONSERVATORY.

Owing to the mildness of the weather, some of the very earliest Camellias may now be coming into bloom, and where this is the case take care to keep as low a temperature as possible, in order to prolong their beauty. All drip must be avoided. The general collection will soon be making a fine display. They should, therefore, receive careful attention as to watering with tepid weak liquid manure. Let them not, however, receive a drop until they are really in want of it, and then give it liberally. If in the case of over-dryness air bubbles arise, continue to fill up with water until they cease. Let not a drop be spilled on the conservatory floor at this period, and give a little air at back all night, in order to let atmospheric humidity pass off. See that early-flowering Cinerarias have the lightest place in the house, and be kept close to the glass. Crowding is very prejudicial to this plant. Let plants of Eranthemum pulchellum coming into bloom have abundance of water and a warm situation. Early Hyacinths will also soon be in flower, and with care a succession of them may be kept up till spring. For late-flowering bulbs the best pots are those 5 inches in diameter (48's) for one bulb, and 6 or 7-inch pots for three bulbs, and where a fine display is desired, three grown together in one pot secure that object much better than single bulbs. For potting, the soil should be as rich as possible, such as one-half fresh loam cut from a pasture, with the turf decayed in it, well-decomposed cow or horse dung, and a small quantity of sand well mixed. Drain efficiently, and after filling the pots lightly with the soil recommended, or, if it cannot be had, the richest and lightest at command, place the bulbs upon the surface, slightly pressing them into the soil. After watering, if the soil is not sufficiently moist, set the pots out of doors on a dry bottom, and cover them with old tan, ashes, &c. After remaining there for a month the bulbs will be sufficiently rooted to render it safe to remove them to a gentle bottom heat of about 55°, introducing the pots in numbers proportionate to the demand at intervals of about a fortnight.—W. Keane.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Celery.—Took the opportunity of earthing-up the last piece of Celery, placing dry ashes and burnt earth round the stems of the plant. As yet we have not had a single plant that was not fit for table use. When we lose at all, we expect it will be by damping, and not by bolting. Our last bed has had little earthing-up. We planted it out chiefly in the hope that it might come in for soups, &c., in spring, rather than with the hope it would be of much service in the salad bowl. Had we the chance of plenty of dry slubble or dry litter, we would pack it firmly among the plants of our Celery beds, and then we would need to be less careful in protecting from frost. Though as yet we have not had enough of frost to collect ice for the ice house, we have thrown a little litter several times over the Celery beds. We find the Celery keeps all the better if the exposed leaves do not suffer much from frost.

Root Crops.—All our roots, with the exception of Parsnips, are now safely under cover. Carrots are never so good if left in the ground in mild weather so long that the fibres begin to come from the sides. Beetroot is easily injured by frost, and in our case we find that when the roots have come to their best they are apt to be injured by rats, which make as much havoc with the crowns as rabbits do with the sunny side of Turnips. Where there is plenty of room, all such roots may be well kept in small heaps. To make the most of shed space, they are generally sorted, and built in narrow heaps packed in dry sand. For this purpose sand, or burned or dried earth, is the best, and sawdust, whatever the nature of the wood it come from, is the worst. It deteriorates flavour, and is apt to become heated to such an extent as to cause the roots to decay. When dry sand, &c., is not to be had, we have found no better plan than building in layers, each layer being separated from those next it by layers of dry twiggy branches, and of these the Larch and the Spruce are, perhaps, the best. These keep the roots long fresh and cool by the free ingress of air. Carrots keep longer juicy and sound if a thin slice be removed with the top. If not done now, it may be done any time in January or February. When Carrots are kept for seed, the tops must remain entire.

FRUIT GARDEN.

We have had acceptable rains, none too early, as water was becoming scarce in this neighbourhood, many large ponds being quite dry. The ground is now more suitable for all kinds of planting. Planting fruit and forest trees, pruning, tying, &c., were entered into somewhat in detail some weeks ago, as well as replanting and root-pruning, and there is nothing much we could add.

Being apprehensive of wet, we had the remainder of our Strawberry plants plunged in leaves on a vinery border, and some old lights placed over them. Placed also in a heated pit plants showing, and others on shelves where they would be gently excited; also filled a frame where there is a gentle bottom heat, the pots standing on the surface, not plunged, as much bottom heat would be injurious now in the case of pots well filled with good roots. Removed yellow leaves and any berries inclined to damp in the late vinery, and gave a little fire heat with top air in dull drizzly days, allowing the fire heat to decline towards evening. Gave front air, and only sparingly, in clear mild days. We have been a little troubled with rats gnawing the Vine stems that come through the front wall. We never knew them meddle with stems of Vines planted inside the house—a good additional reason, joined to others, why it is advisable that Vines should be so planted. A press of other matters has prevented our going on with pruning, &c., as we would have wished, for the spring always brings more than enough of work with it.

ORNAMENTAL DEPARTMENT.

Cleaned, swept, and rolled, as a mere matter of routine. This is very suitable weather for fresh turfing and ground work of all kinds. Collected leaves in the park, knowing that if a few dry and windy days should come we should see no more of the leaves, and every season finds us short of leaf mould for many purposes. Nothing else will exactly take the place of leaf-mould compost when well exposed to the air and sweetened. It is, however, not safe for many purposes, if used when only about half decayed. We had some potting done with a little of what seemed sweet half-decayed leaves put over the drainage, and we had to take the plants out and repot them, as the spawn of various fungi were filling the leaves and spreading through the soil. We believe fungi and mildews develope themselves in borders and quarters from using such material too fresh, and in a rank unsweetened state. We may thus easily find an enemy where we thought we had a sure friend.

We find nothing so good for *drainage* as a little clean fresh moss over the crocks, one crock over the hole, and the moss is often more effective than a handful of crocks without it. It retains moisture, and parts with a superabundance of it. When

worms are likely to be troublesome, and metal bell-caps are not need, the convex side of a good-sized piece of broken pot should go over the hole in the bottom of the pot, a few smaller pieces over that, then a little clean moss, and just a dusting of fresh soot. You cannot place a convex crock so firmly over the hole in the bottom of the pot but the water will find its way ont, and yet scarcely the smallest worm can wriggle itself in, and the moss for a long time will prevent the earth passing among and so choking the drainage. All these evils are apt to take place, besides the spreading of spawn, when half-decomposed tree leaves are used for this purpose. If we had to use them at all we would use them fresh and dry. Chopped, slightly charred straw, is the best substitute we have found for moss, but it is not equal to it. Small sifted charcoal, deprived of the dust, makes a capital drainage above the crock and beneath the moss. From an eighth to a quarter of an inch in thickness, when pressed by the earth, would be enough of moss for a small pot, and more in proportion for larger ones, as nothing is gained from the moss worth speaking about, except assistance to free drainage, and equalising the moisture in the soil.

The dull moist weather has rendered necessary careful watering, and looking after damped leaves. The bedding Pelargoniums, &c., taken up saved us most of this trouble, as all the leaves were removed. Potted and placed a lot of Lily of the Valley in a mild hotbed, selecting the best crowns as frequently detailed. Cinerarias, kept cool in a pit, have never yet been touched by the green fly. A cool atmosphere, and, above all, a cool bottom are what they delight in, and what no insect cares for.

Flues.—In the first column, page 423, below a line in italics, "of the top of the flue," should be "of the bottom of the flue," a very great difference in general, though not so much as respects the flue alluded to. In the flue mentioned, and with our consent, in no flue whatever are there any plasterings inside.—R. F.

COVENT GARDEN MARKET.—December 1.

There has been a slight advance in some things, but the general tone of the market is not at all what we usually experience at this season. Good hothouse Grapes, both Muscats and Hamburghs, are in request, but Pines are much in excess of the demand. The Potato trade is very dull, the supply by rail being very heavy.

TO CORRESPONDENTS.

Books (*Francis Allum*).—"The Garden Manual;" you can have it post free from our office if you enclose twenty postage stamps with your address.

Binding the Journal of Horticulture (*A. L.*).—We have no covers for two volumes in one. We had them made once, but there was too little demand for them.

Apple Trees from Pips (*Deerhound*).—They will bear without grafting. The Royal Agricultural Society's Journal can be obtained in numbers. The price is 6s.

Grapes (*W. H. W.*).—The reason of their not colouring was the Vines having been allowed to carry too heavy a crop. The bunch of Muscat of Alexandria, though small, had good-sized well-flavoured berries.

Vines not Productive (*F. D. J.*).—In such a case we would advise what we want to do ourselves—to clear out at least a part of the house, make a new border, or part of it next the house, and plant afresh. As what would be likely to improve the old Vines, we would take away as much of the surface soil as we could without injuring the roots, and add 3 or more inches of fresh compost of fibrous loam, with a third of equal parts of broken bones, charcoal, and lime rubbish, with a little quicklime as a dressing, if the old soil of the border is rich and effete. Then put on a foot or 15 inches of leaves, litter, or fern, just to throw a little heat into the surface of the border, and encourage the roots to send fibres into the fresh material. Such a border could be mulched in summer, and treated next season in a similar manner. The radical cure would be fresh planting, or replanting the present Vines in fresh material.

Dressing Vinery Border (*Muscat*).—By all means remove the old dung from your Vine border before replacing with the fresh manure; but in doing so leave any little part where the Vine roots have come through.

Management of Ground Vinery (*J. W.*).—We would leave the lights on the ground vinery all the winter; never move them, unless to do the necessary work. Much of the success depends on having the wood well ripened and hardened in autumn, by giving the Vines all the heat from sunshine possible without scorching, which is scarcely probable with the ventilation at the sides. We hope you will be more successful next season.

Forcing a Vine (*A. K.*).—The Vine from which the leaves are only just falling will hardly be in a fit state to force to ripen the fruit in May, especially as the roots are in an outside border; but as you do not mind weakening the Vine, you may, if the wood is ripe, clear away all the leaves, and in a few days prune the Vine, keeping the house cool, and in a week's time, after the Vine is pruned, there should be 2 feet of hot dung placed on the border, and over that a foot of dry litter or straw, with a slope so as to throw off the wet. The dung on the border should be supplemented with fresh as required, so as to give a gentle warmth to the border, and consequently to the roots of the Vine. In a fortnight after the border is covered you may commence forcing, the house being closed, as it is termed, and by maintaining a good heat, after the Vines are in leaf, you may have fruit at the end of May or beginning of June.

Bones for an Outside Vine Border (*W. B. B.*).—You could not have a better manure than bones for a Vine border. We suppose they are old and dry, and only need to be broken small. You may break them with a heavy hammer, but they are much better broken at a boneworks, where they are converted into what are known as half-inch bones. The best time to apply them is in February, or if the weather be wet, as soon after as the soil is not claggy. For the size of border you name, 4 cwt. will be a sufficient dressing, applying the bones broadcast, and forking them into the border as deeply as can be done without injury to the roots.

Evergreens for a House Front (*F. M. C.*).—As you confine us to evergreens, we must omit many climbers which would be suitable. The following are evergreen climbers or sub-scandent plants, suitable for a wall with south aspect:—Billardiera scandens, B. longiflora, Berberidopsis corallina, Bignonia radicans, Caprifolium brachypodum aureo-reticulatum, C. sempervirens floribundum, Jasminum revolutum, J. Wallichianum, Lardizabala biternata, Passiflora cærulea, Ceanothus azurens, C. floribundus, C. integerrimus, C. papillosus, Escallonia macrantha, E. glandulosa, Garrya elliptica, Ligustrum japonicum and variegated sorts, and the Exmouth variety of Magnolia grandiflora.

Camellias and Azaleas for a Cold Frame (*A Beginner*).—Unless you can exclude frost by a covering of mats or straw they would not succeed, especially the Azaleas, as to do well they require heat to make new growths and set the buds. However, they will endure a few degrees of frost without injury, and it is well worth a trial. Your plan would be to secure plants now set with buds, and place the pots on coal ashes, surrounding the pots with hay secured by matting, to protect the roots from frost. During winter the soil should only be kept moist, and air should be freely given in mild weather to dry up damp, no air being admitted when the temperature out of doors is below 40°. Protect at night from frost, and during days of severe frost the plants ought also to be protected, not uncovering them as long as the frost continues, unless the external temperature exceed 40°. After flowering, place in the frame, potting if required, and sprinkle with water morning and evening, watering copiously, and not allowing the soil to become dry. Air should be given moderately, and shade from bright sun until the growth is complete; then admit air more freely, and omit the sprinkling with water overhead, drawing off the lights, especially at night, and shade from very bright sun by a light covering up to September, when they should have full exposure until the nights become frosty in October, still continuing to give air whenever an opportunity offers, protecting from frost as before. *Camellias:* Alba plena, white; Bealii, crimson; Fimbriata, white; Valtevaredo, rose; Alexina, white, striped and blotched with carmine; and Teutonia, pale rose, striped white. *Azaleas:* Amœna, rosy purple; Gledstanesi, white, striped red; Rosea elegans, rose; Magnifica, white; Stanleyana, rosy scarlet; and Etoile de Gand, shaded salmon, white margin.

Azaleas Wintering in Cold Pit (*Azalea*).—The Azaleas will winter safely in a cold pit if you can keep the frost from them, which you may do if the sides of the pit be banked up with ashes, and a sufficient covering placed over the lights. They would, however, be more safely wintered in a cool house, where a little fire heat could be given them in severe weather, and you may retard the plants by moving to the cold pit in February, shading and keeping cool.

Destroying Woodlice in Forcing Pits (*Subscriber to Journal*).—Firm the soil round, place a little hay there, and early in the morning pour boiling water on the hay and wall. You will thus kill thousands. Repeat this a few times. If this plan cannot be adopted, put boiled potatoes, enveloped loosely in a little hay, at the bottom of small flower pots. Lay the pots on their sides near the haunts of the woodlice, and in the morning shake out the contents of the pots into a bucket of boiling water. This persisted in will soon thin their numbers. A few toads are good in pits and houses infested with woodlice.

TECOMA JASMINOIDES NOT FLOWERING (*Ignoramus*).—The want of flowers is, perhaps, a result of too-vigorous growth, the soil being too rich, and the roots having an unlimited amount of border. The plants do best when the border is restricted to a space about 2 feet wide and deep, and twice that in length, the border being well drained and filled with a compost of two parts fibrous loam, one part of sandy peat, and one part of leaf soil, with a free admixture of sharp sand. When growing, water the plants freely, and keep the shoots from becoming too crowded by thinning them out as required, and training before the shoots become entangled. When a good growth is made, give no more water than will keep the shoots and foliage fresh, otherwise keep the plants dry, and give them all the air practicable, with as much light as possible. Keep the plants dry during the winter, thin the shoots in spring, and if you keep them from becoming too much crowded, we think you will have flowers next year.

RIBBON BORDER (*H. B.*).—Your proposed mode of planting will do something to bring in Hyacinths, Van Thol Tulips, Crocuses, and Snowdrops more together, but Nature will have her way. To have a blaze of bloom and no fading flowers near, why not plant in beds or groups separately? Do what you will, the bulbs will not bloom all together, unless only one kind is used in a place, and that, too, one kind of one plant. For instance, a bed of mixed Hyacinths will rarely open all on the same day or in the same week.

SLUGS IN A PIT (*H. V.*).—In your turf pit you find the turf brings many slugs, which destroy the cuttings, and you propose taking the plants from the board shelves and setting the pots on, or in, warm tan. The tan, if not too warm, would encourage growth, but it would also encourage damp, and be the very thing for the slugs to nestle in whenever it became the least mild. We would by far prefer the wooden shelves. To get rid of the slugs, we would first examine the pots, and see there was none lodging in the hole in the bottom. They can make themselves almost as thin as a hair, and go in and out of the hole at the bottom of a pot when set on a board. Next we would bait all the sides of the pit with young cabbage or lettuce leaves that had received just a taste of melted butter or dripping, and examine them in the morning. Small heaps of brewers' grains would be rather more attractive. Then, to make quite sure, we would run round our shelves a slight cordon of dry quicklime and soot, which for a time would be as impassable to the slugs as the running stream to the witches. We do not think that the little white worms near the stems of your cuttings and young plants are the cause of their rotting away. However, they will do no good, as tending to disturb the roots and the open free texture of the soil. If not very bad, if the plants need watering, use clear lime water, which will most likely kill the worms. If very much infested, it will be better to turn the balls out and repot in fresh earth. Common worms are very anxious to enter at the bottoms of the pots. A cap over the hole will stop them, and so will a common rounded crock or piece of a broken pot, if the rounded or convex side is placed over the bottom of the pot so as to fill the hole securely. Some small drainage placed over that will insure the free exit of water. We suspect your little worms are larvæ that were in the soil used. We know of no security except destroying all such living things by heat, and then exposing the soil to air before using it. Even already you find there are troubles in gardening.

BURNING EARTH (*Idem*).—To burn earth and weeds, nothing more is required than to make a good fire with some large roots, &c., in it, and as soon as the fire breaks out keep putting on more material.

SIZE OF HORSE CHESTNUT TREES (*J. Anderson*).—In your alluvial soil near Spalding their heads would, probably, be 40 feet in diameter; but, as we said before, vigour of growth and the form assumed by the trees are controlling circumstances which we cannot foretell.

HEATING A GREENHOUSE BY A FLUE FROM A GRATE (*Greenhouse*).—See answers to correspondents at page 425, and "Doings of the Last Week," page 423. Much will depend on the relative position of the grate in the opposite side of the wall, and of the floor of the house to be heated. If the floor is considerably above the level of the grate, there would be no difficulty as respects a flue, if the fireplace of the grate should be so shut in as to leave air only at the bottom. This might be the best plan for a good-sized house—taking the flue into the chimney, but blocking up the old chimney beneath to prevent a back draught. If the house is middle-sized, the fire might be made to draw at once into a fresh small chimney built against the back wall of the greenhouse, and with a reduced opening, say of 4 inches, into the old chimney. In this case the bottom of the present chimney must be stopped to prevent back draught. In such a case, if the fire were used in summer, the new chimney could be stopped and the old one opened. If the house is small, the fireplace could be opened into a brick stove on the other side, say 2 feet square and 3½ feet in height, the opening into the old chimney being made at about 9 inches from the top. This plan might be adopted if the grate and greenhouse floor were on similar levels. If the house is very small, the simplest plan would be to place the curve of two 3-inch pipes bent like the letter U, thus—⊂ in the fireplace, with the open ends 2 or 3 feet in the house. If the fire in the grate were continuous and pretty strong, these pipes might be connected with a cistern, and then you would have hot water. Even with short pipes you would obtain much heat, and the milder it would be at the mouth of the pipes in proportion to their length. Even with a short pipe, if open beneath a stage, &c., a good distance from plants, the dry heated air would be moistened enough before reaching them, or if means were taken to moisten the dry air. If you give us more particulars we will do our best to assist you, though the above and the references will most likely enable you to decide.

HEATING A PROPAGATING HOUSE (*J. C. L.*).—You do not state the size of your house for propagating and for Cucumbers, but so far as we can make out, as the pipes at present at work are outside your bed and pit, we would let them remain where they are for top heat, and take a flow and return through the bed, previously filled with tan, for bottom heat. Two 3-inch pipes would do admirably for such a narrow pit, either by themselves, surrounded by stones, on the gravel, or laid in a tank; or you might have no pipes further than a flow and return into a divided tank. A brick and cement tank will answer perfectly. Two bricks-on-bed will answer admirably for the sides, and a brick-on-edge for the centre, with a tile to make the level right. The tank had better be 2½ feet wide at least. It would be best to have the bottom heat independent of the top heat. The tank covered with slate would answer all the purposes stated, but for Cucumbers it would be well to have some rough material over the tank, such as clinkers, &c., before placing the soil on. For propagating, sand, &c., would be needed for plunging the pots. The boiler would, no doubt, do the additional work if properly placed. See what was lately stated in answers to correspondents. Were we in your case, and used pipes, we would not trouble ourselves with the tank. If we resolved on a tank, though the pipes would make it surer, we would make the tank well, and be satisfied with it. A small wooden tank, like a brewer's cooler, some 4 inches deep, covered with slate, would last a long time if kept full of water and not painted.

MANAGEMENT OF CORDON PEACH TREES (*J. J H.*).—"You do not state if they are under glass or in the open air. This is important, for I have distinctly declared in the 'Modern Peach-Pruner' that I do not recommend Peach cordons for the open wall, unless under a system analogous to that of Dubreuil's first. This plan, I think, is now being carried out—modified by his own judgment—by Mr. Radclyffe, and I am much interested in the result. He calls it 'herring-bone,' and it gives a greater lateral scope to the spurs and shoots, thereby increasing the vigour of the whole tree. Under glass, however, we require a closer pruning, and I recommend pruning to four leaves as soon as six fully-grown leaves are formed. The two upper buds of these four may burst, but the two lower ones will remain dormant, and become fruit-bearing. The second growth, when four leaves are made, is reduced to two leaves; the third growth is reduced to two leaves, or allowed to elongate, according to the vigour of the tree. In forming a Peach cordon during the first year, however, only equalise the shoots to 6 or 8 inches, and at the winter regulation cut back to two healthy eyes, each of which will next summer send out a shoot, which two shoots are henceforward to bear alternately. One shoot, left long, bears the fruit; the other, cut back, carries the succession wood. This refers to diagonal cordons under glass; potted trees must be more closely pinched back, say to three leaves instead of four. But the great point is to secure sufficient shoots on each spur to be able to prune on the 'alternate system.' This never has failed me.—T. C. EBÉHAUT."

APPLES ON SOUTH WALL (*Centurion*).—The Red Astrachan being an early Apple is altogether unsuited for a south wall, and having it there is a great waste of space. It will be far better to move it, and grow it in the form of an open espalier as you propose, and the same with the Yellow Bellefleur. We have no acquaintance of Monstrueuse d'Amerique. We should think, however, it would prove the most suitable of the three. If you really wish for Apples on your south wall, the best varieties you could cultivate are Calville Blanche and Reinette du Canada. The Elruge Nectarine is the best variety for general cultivation.

WINTER-DRESSING APPLE, CHERRY, AND PLUM TREES (*J. P.*).—When the trees are pruned, dress every part of them with a composition formed of 8 ozs. soft soap, 1 lb. flowers of sulphur, with sufficient tobacco water to form a thin paint. The tobacco water of the shops may be used, or it may be made by pouring a gallon of boiling water on 8 ozs. of tobacco, letting it stand until cool, then strain. To take away the colour of the sulphur, add enough soot to the gallon of tobacco water, besides the sulphur and soft soap, and in that way form a thin paint, with which dress the trees, rubbing it well into every crevice, taking care not to dislocate the buds. We have no experience of spent logwood from a drysalter's, but should not think it desirable for fruit trees.

LACHENALIA, TRITONIA, AND TIGRIDIA IN POTS (*A Young Countryman*).—The Lachenalias are greenhouse bulbs, and should be grown on shelves near the glass. They should be potted as soon as growth commences. Continue to water them as long as the leaves remain green, but no longer; keep them dry until they begin to grow, which usually is at the end of summer. The winter temperature should be from 40° to 45°. The soil most suitable is sandy peat two-thirds, and one-third fibrous loam, with a free admixture of sharp sand. The bulbs are best surrounded with sand, especially those of the small species. In potting, cover the bulbs to the neck, and provide good drainage. Tritonias should be potted in October, not disturbing the ball, except for the purpose of division, and after potting water so as to settle the soil about the roots, and keep the soil moist even in winter, and the plants secure from frost. They may be grown successfully in a cold pit or cool greenhouse, placing them out of doors after May, watering them copiously, and sprinkling them overhead frequently to keep down red spider. A compost of four parts fibrous loam, two parts sandy peat, one part leaf soil, and one part of old cow dung, with a free admixture of sharp sand, and good drainage, will grow them well. Tigridias are hardy bulbs, but may be grown in pots, in a compost of two-thirds sandy fibrous loam, and one-third leafsoil. They should be potted in March, if they have been kept over the winter in soil in a cool, dry house, but safe from frost. They should be well watered, and may be planted out in May, taking them up at the end of summer, potting, and keeping them dry during the winter.

GOLDEN FEATHER PYRETHRUM PROPAGATION (*X. X.*).—You may take cuttings of the plants in February or early in March, and in a gentle heat they soon root. The shoots that come from the base of the plant should be slipped off; and after their base has been pared smooth with a knife, they may be inserted in sandy soil and placed in a gentle hotbed. The plants will be fit to put out in April. Seed sown early in spring will give plants for putting out in May, and seedlings are not so liable to form so great a profusion of white starry flowers as cuttings, and on this account we think seedling plants best; but cuttings are generally the best in point of colour of foliage.

CENTAUREA CANDIDISSIMA PROPAGATION (*Idem*).—We presume you have the plants in pots. Place them in a house where there is a gentle heat (50°) in February, and when the side shoots are 3 or 4 inches long take them off close to the stem, pot in sandy soil, surfacing the pots with sand, and place them in a gentle hotbed of 70°, keeping them close, but being careful not to overwater, or the cuttings will damp off. They will root in about three weeks or a month, and be good plants by the end of May. There is no difference between C. candidissima and C. gymnocarpa.—G. A.

PASSIFLORA QUADRANGULARIS FRUIT (*J. B.*).—Dr. Hogg in his "Vegetable Kingdom" says, "P. quadrangularis is the common Granadilla or Granadilla Vine. It is a native of Jamaica and South America, and produces a large fruit of an oblong shape, 6 inches in diameter, and 15 inches in circumference. The skin is of a greenish-yellow colour, and, when ripe, soft, leathery, and very thick, but contains a succulent pulp of a purple colour, which is the eatable part. The flavour is sweet, and slightly acid, and is very pleasant to the taste, especially in a hot climate. It is generally eaten with wine and sugar." The blossom is

that of Nerine undulata; the Pinus, P. Pallasiana, and the Picea, P. grandie.

Cupressus variegated (*J. B.*).—We do not know a Cupressus of the name you give, but it would likely succeed from cuttings put in now in sand in a cool house, covering them with a hand or bell-glass, and keeping the soil moist but not saturated. It would have been better had the cuttings been put in earlier in the season, but they will yet succeed. They would no doubt retain the variegation the branch at present exhibits.

Pyramidal Pans for Selaginellas (*E. L. J.*).—We do not know where these may be had in London, but they may be had of most dealers in flower pots.

Lilium auratum and lancifolium Potting (*Rev. W. H.*).—It is now a good time to pot these bulbs if not done before, giving them an increased size of pot, and in potting do not disturb the ball beyond removing any loose soil without injury to the roots. The soil ought to be kept moist during the winter, and when the plants are growing they should have a light, airy position. They succeed in a cold pit, protection being given from frost, or they may be kept in a cool greenhouse. Your other question is answered in "Our Letter Box."

Indiarubber Plant's Shoots Dying (*Amateur*).—It is owing to the plant not having sufficient heat to mature the growth, and it dies back from the cold and damp. Give more heat and moisture in summer, so as to secure a good growth; it will then succeed in a greenhouse temperature in winter.

Cyclamen Seed Sowing (*Idem*).—You do not say what variety you wish to grow; but we advise the seed to be sown now in pans well drained and filled with a compost of two parts fibrous sandy loam, one part peat and leaf soil, and one part sandstone, broken small, and silver sand, the whole well mixed. Level the surface, scatter the seeds evenly, and cover with fine soil. Water gently, covering the pan lightly with moss, and place it in a house with a temperature of from 50° to 55°. Keep the soil moist and near the glass, admitting air freely when the plants appear. When they have made two or three leaves, pot them off singly into small pots, and in summer remove them to a cold frame, keeping moist, and shaded from bright sun. Pot as may be necessary into larger pots, and take in-doors at the end of September, placing the plants on a shelf in a house with a temperature of 45°; and with due supplies of water, and potting as required, you may probably flower them the spring after next; if not, let them go to rest in summer, potting them when they begin to grow. They will flower in autumn, winter, or spring, according to the sort. In potting cover the corm with soil. A little old cow dung may be mixed with the soil. Good drainage should be given.

Tea Roses in Pots (*Calcaria*).—There is very little doubt that Tea Roses would succeed very well planted in the open ground and protected during winter with a curate's ground vinery. Care should be taken to keep the air as dry as possible, and to raise the sides of the ground vinery sufficiently to allow plenty of ventilation. During severe weather a little clean straw might be thrown to the sides of the frames, and it would be better if they were placed to face east and west, so as not to have the full sun from the south in the spring. The soil should be well forked over and manured, and if at all heavy a liberal supply of leaf mould should be added, the whole mulched for the winter with short manure, and in the summer with cocoa-nut fibre, as under a frame the roots would be more inclined to draw to the surface and would suffer from the summer's sun. The plants ought not to be nearer than 18 inches, and the stronger shoots might be pegged. The following sorts on the Manetti stock would answer well with this treatment:—La Boule d'Or, Louise de Savoie, Madame Willermoz, Madame de Vatry, Souvenir d'un Ami, Monsieur Furtado, Narcisse, Niphetos, Adam, Josephine Malton, Madame Bravy, and Madame Margottin.

Leaf of Seedling Pelargonium (*A. R.*).—The diameter, 8½ inches, is very large.

Border Tiles.—"*E. K.*" and "*C. Princep*" wish to know where the border tiles mentioned in page 419 are to be obtained.

Names of Plants (*Rev. R. H. C.*).—Asclepias curassavica. (*Filices*).—2, Polypodium appendiculatum; 6, Pteris serrulata; 9, P. cretica, the typical green form. The other numbers not received by us. (*A Surrey Subscriber*).—Lamium maculatum. (*W.*).—Dendrobium Gibsoni and Maxillaria Parkeri. (*Agra*).—Asplenium Adiantum-nigrum. (*Devonia*). 1, Asplenium Adiantum-nigrum, the typical form; 2 and 3, A. Adiantum-nigrum, var. obtusum; 4, A. Trichomanes. (*R. Buck*).—Vallota purpurea. (*W. S., Birkenhead*).—Dendrobium heterocarpum, otherwise D. aureum. The other Orchid we have not yet recognised.

POULTRY, BEE, AND PIGEON CHRONICLE.

A QUID PRO QUO.

Knowing that poultry shows very seldom pay, "Egomet" might admit that committeemen work hard and put their hands in their pockets for the improvement of our pets and the good of the poultry world generally, and that committeemen consider that improvement and good a *quid pro quo*.

Thus far admitted, "Egomet" might allow a committeman the pleasure of a silver cup if he can fairly win it. He has to pay the same entry fees, is subject to the same rules and regulations, has had the same chance of trouble and expense to procure, has the same desire to improve, his stock as his fellow amateurs, and is subject to the dictum of the same judge. Then why should he not honestly exhibit? Having paid his entry fees, &c., why should he not have the *quid pro quo*—a fair chance of the prizes? "Oh! Committeemen should be above suspicion," is usually the answer. But should they be suspected? If they are, it must be imagined that our judges are corrupt, conniving at some secret arrangement of awarding the prizes to as corrupt committeemen. If they are not to be trusted in this, are they to be trusted in anything? and the wonder is that the suspicious should trust their property in their hands.

In the spirit of an enthusiastic brother amateur I argue that it is better to allow committeemen to exhibit at their pleasure than for poultry shows to decline, for decline they must and will if this obstructive course be persisted in. Exhibiting committeemen would rather be off than on a committee if they could not show with a fair chance of the prizes. Their pride is their prize fairly won. Supposing it were arranged to "Egomet's" satisfaction, and a committeeman never showed again at his own show, what would be the result? Why, Birmingham, that is strongest in one or two particular breeds, would never show her best birds in those breeds. Bristol Spanish are known the poultry world over, but then you would have to visit some other town to see them, as they could not be shown at a Bristol show. Nearly all the great shows follow suit, and where you would expect the strongest native exhibition you would find little or none. Would this be fair to honest men, saying nothing about the knaves beyond? Watch them, prove them, expose them; after exposure let exhibitors decline to enter again at that show as long as that man is connected with it, and it will tell its own tale and gratify—An Old Committeeman.

I think it will be admitted that, as a rule, the members of a committee are greatly interested in the various varieties of poultry and Pigeons; then why should they, simply because they give their time and interest in promoting an exhibition in their neighbourhood, be debarred from showing, and thus be probably deprived of the pleasure of success, which would doubtless be considered greater at home than abroad? What does it signify to whom the prizes are allotted, provided the best birds win? and it appears to me to be casting a slur upon the judges, who are generally well known to the public, to attempt to insinuate they would be partial in their awards. I am an exhibitor, and certainly care but little to whom the birds belong that win, if they are superior to mine, and think that, whether committeemen or otherwise, they are fairly entitled to the merit and advantages derived from the superiority of their stock.—No Committeeman.

BIRMINGHAM POULTRY SHOW.

We must reserve our reporter's notes until next week, but will now publish a few remarks and statistics with which we have been favoured:—

The reduction in the number of pens exhibited is, doubtless, owing to the additional sixpence, for there was an increase in the number of Pigeons, on which no advance of charge for

exhibiting was made. The following shows the variations in the numbers of the different varieties :—

	1862.	1863.	1864.	1865.	1866.	1867.	1868.	1869

1867	220 „	891
1868	203 „	806
1869	213 „	847

Dorkings still prevail, the birds excellent; and Mrs. Arkwright may be justly proud of the great pre-eminence of her birds. *Cochins*, though fewer in number, and *Brahma Pootras*, were very superior classes. *Malays* are too ungainly ever to prevail, despite increased prizes. The *French varieties* were mostly good, and are evidently ascending to be cultivated as useful and not merely fancy birds. *Spanish*, fewer in number, were never surpassed in excellence. *Hamburghs* of all the varieties were superior. *Polands* were more numerous than usual, and even Mr. Adkins was shorn of some of the honours. In *Game*, Black-breasted Reds, as usual, far outnumbered the other varieties, and the cock exhibited by Mr. C. Challoner cannot be surpassed. *Bantams*, few but good. Aylesbury *Ducks* still are increased in size, but not in excellence of appearance. Mrs. Seamons' first-prize pair of birds weighed 17¾ lbs., last year they weighed 17½ lbs. The second-prize pair, Mrs. Burrell's, weighed 17 lbs. 7 ozs.; and Mr. Fowler's third-prize pair, 17 lbs. 2 ozs. Rouen Ducks were very superior. The first-prize pair weighed 18 lbs. 14 ozs. The first-prize weight last year was 19¼ lbs. The second-prize pair weighed 17 lbs. 12 ozs., against 18¼ lbs. last year.

White *Geese* were very few and rather inferior. The weights were :—Old birds, first prize, 53½ lbs.; second prize, 52 lbs.; birds of 1868, 55 lbs. and 51 lbs.; birds of 1869, 50¼ lbs. and 42 lbs., against 50 lbs. and 40½ lbs. last year. Grey *Geese* were more numerous and better than their White brethren and sisters. Old birds weighed 57½ lbs. and 53½ lbs.; last year, 55 lbs. and 51 lbs.; young birds, 48¾ lbs. and 46½ lbs.; last year, 50 lbs. and 40½ lbs. *Turkeys*, like Geese, are chiefly valuable in proportion to their weight. Heaviest old cock this year 34¾ lbs.; last year 32 lbs.; young cock, 23¾ lbs., last year 24 lbs. Pair of hens, this year 37¾ lbs.; last year 37½ lbs.; poults this year 28 lbs. 2 ozs.; last year 29 lbs.

As usual, the prize pens were offered by auction by Mr. Lythall, the prices realised being—Pen 62, Mrs. Arkwright's Coloured Dorking cockerel, £12; 29, Earl of Chesterfield's Coloured Dorking cockerel, £5 10s.; 73, O. E. Cresswell's Coloured Dorking cockerel, £5; 188, J. Anderson's Coloured Dorking pullets, £4; 212, Lord Bagot's Silver Grey cock, £3 15s.; 219, Lady Bagot's Silver Grey cock, £4; 230, Miss Endall's Silver Grey cock, £5 10s.; 240, Rev. George Gilbert's Silver Grey pullets, £2 12s.; 267, Miss Topp's White Dorking cock, £3; 392, J. Cattell's Cochin-China hens, £10; 499, T. Amies' Cochin-China cockerel, £3 3s.; 555, A. Swindell's White Cochin-China cockerel, £8 15s.; 898, Mrs. Wilkin's Houdan cock, £2; 941, H. Lane's Spanish cock, £10; 1089, H. Beldon's Silver-pencilled Hamburgh cock, £5 15s.; 1153, A. Wood's Silver-spangled cock, £10 1420, E. C. Gilbert's Black-breasted Red Game pullet, £5 15s.; 1485, T. Burgess's Game hen, £5 5s.; 1688, Mrs. Hayne's Black East Indian Ducks, £4; 1895, C. Bamford's Geese, £5 5s.; 1931, Rev. T. L. Fellowes' Turkey cock, £5 15s.; 2075, Mrs. Ladd's Pouter Pigeon, cock, £11; 2270, G. South's Turbits, £6; 2291, G. South's Dragoons, £3 15s.; 2372, S. Taylor's Antwerps, £3. There were a large number of sales in the other classes.

DORKING (Coloured, except Silver-Grey).—*Cocks.*—1, Mrs. Arkwright's Scarsdale, Chesterfield. 2, J. Dewry, Burton-on-Trent. 3, Admiral W. Hornby, Knowsley Cottage, Prescot. 4, J. Martin, Claines, Worcester. *hc*, Admiral W. Hornby; Hon. H. W. Fitzwilliam, M.P., Rotherham; R. Yardley, Marke: Hall, Birmingham. *c*, T. Statter, Whitefield, Manchester.

DORKING (Coloured, except Silver-Grey).—*Cockerels.*—1 and Cup, Mrs. Arkwright. 2, J. Anderson, Meigle, N.B.; 3, Earl of Chesterfield. 4 J. Longland, Northampton. 5, O. E. Cresswell, Hounslow. 6, Miss E. Whittington, Henley-in-Arden. *hc*, L. Patton, Hillmorre, near Taunton; Gunson and Jefferson, Whitehaven; H. Crossley, Halifax; R. Yardley; Rev. E. Cadogan, Warwick; T. Statter; J. White, Northallerton, Yorkshire; S. Ball, Wolverley, Kidderminster; E. Shaw, Oswestry; *c*, L. Patton; Rev. E. Cadogan; J. White; J. Martin, Worcester; O. E. Cresswell.

DORKINGS (Coloured, except Silver-Grey).—*Hens.*—1, J. Fox, St. Bees, Cumberland. 2, L. Patton. 3, R. W. Beachey, Kingskerswell, Devon. 4, W. W. Ruttlidge, Shortend, near Kendal. 5, J. H. Wilson, St. Bees, Whitehaven. *hc*, D. C. Campbell, M.D., Brentwood, Essex; C. Morris, Grassendale, Liverpool; Mrs. Arkwright. *c* J. Anderson; Gunson and Jefferson; L. Patton; J. Fox.

DORKINGS (Coloured, except Silver-Gray).—*Pullets.*—1 and Cup, H. Crossley; 2 and 5, Mrs. Arkwright. 3, T. Statter. 4, R. W. Beachey. 6, J. Anderson. *hc*, Rev. A. K. Cornwall, Rencombe; J. H. Wilson; J. Anderson; F. Parlett, Chelmsford; L. Patton. *c*, Gunson & Jefferson; J. Martin; Mrs. Hurt; W. W. Ruttlidge; J. Drewry; F. Parlett.

DORKINGS (Silver-Grey).—*Cocks.*—1, T. Raines, Stirling. 2 and 4, Lady Bagot, Rugeley. 3, R. Smalley, Lancaster. 5, Lord Bagot. *hc*, Lord Bagot; R. Smaller; J. Horton, Shirley. *c*, R. D. Holt, Windermere; H. Yardley; R. Smalley.

GAME (Brown and other Reds, except Black-breasted).—*Hens.*—1, T. Burgess. 2, C. W. Brierley. 3, C. Homfray. 4, J. Wood.

GAME (Brown and other Reds except Black-breasted).—*Pullets.*—1, S. Matthews. 2, W. Boulton, Dalton-in-Furness. 3, C. W. Brierley. 4, Miss E. Crawford, Southwell, Notts. 5, J. Wood. *hc*, G. R. Smith.

GAME (Duckwings and other Greys and Blues).—*Cocks.*—1, S. Matthews. 2, C. W. Brierley. 3, C. Chaloner. 4, W. Dunning.

GAME (Duckwings and other Greys and Blues). — *Cockerels.* — 1, C Chaloner. 2, Col. W. Blackburne, Leamington. 3, S. Matthew. 4, C. Chaloner. 5, W. Dunning.

GAME (Duckwings and other Greys and Blues).—*Hens.*—1, F. Watson. 2, W. Bradley.

GAME (Duckwings and other Greys and Blues).—*Pullets.*—1, H. C. Parkes, Quadrant, Birmingham. 2, H. C. & W. J. Mason, Drighlington, near Leeds. 3, H. Beldon. *hc*, Miss J. Cooper; J. Mitchell, Moseley.

GAME (Black and Brassywinged, except Greys).—*Cock.*—1 and 2, R. Robbins, Kenilworth. 3, Capt. W. G. Webb, Tamworth.

GAME (Black and Brassywinged except Greys).—*Hens or Pullets.*—1 and 2, Capt. W. G. Webb. 3, Rev. G. S. Cruwys, Tiverton.

GAME (White and Piles).—*Cock.*—1 and 2, Rev. F. Watson. 3, J. W. Thompson.

GAME (White and Piles).—*Hens or Pullets.*—1, Rev. F. Watson. 2, H. C. & W. J. Mason. 3, J. Sichel. *hc*, Rev. F. Watson; W. Johnson, Stanley, near Liverpool. *c*, Rev. F. Watson.

BANTAMS (Gold-laced).—1, T. C. Harrison, Hull. 2, Rev. G. S. Cruwys. *hc* and *c*, M. Leno.

BANTAMS (Silver-laced).—1 and 2, M. Leno. *hc*, Rev. G. S. Cruwys. *c*, T. C. Harrison.

BANTAMS (White Clean-legged).—1, Rev. F. Tearle. 2 and *c*, E. Prichard.

BANTAMS (Black Clean-legged).—1 and 4, H. Draycott, Humberstone, near Leicester. 2, R. B. Riley, Halifax. 3, M. E. Cambridge, Bristol. *hc*, T. C. Harrison. *c*, W. A. Taylor.

BANTAMS (Any other variety except Game). — 1, Hon. C. E. Finch, Coventry. 2, Mrs. Woodcock. *hc*, J. Beasley, Northampton; H. Savile. *c*, J. Watts.

GAME BANTAMS (Black breasted Reds).—1 and Cup, J. Crossland, jun., Wakefield. 2, W. B. Jeffries, Ipswich. 3, G. Smith, Staveley, near Chesterfield. 4, H. Shumach, Southwell. 5, R. Brownlie, Kirkcaldy. *hc*, Rev. A. K. Cornwall; J. Adkins, jun., Walsall; W. Hinchlieff, Southwell; W. F. Entwisle. *c*, H. Ashton; T. Sharples, Rawtenstall.

GAME BANTAMS (Brown and other Reds except Black-breasted).—1, Miss Crawford. 2, H. Shumach.

GAME BANTAMS (Any other variety).—1 and 3, H. Shumach. 2, J. Crosland, jun.

GAME BANTAMS (Black-breasted and other Reds).—*Cocks.*—1 and 4, W. Hinchlieff. 2, J. W. Morris, Rochdale. 3, J. Anderson. 5, T. Sharples. *hc*, H. Shumach; Bowman & Fearon. *c*, Capt. Wetherall.

GAME BANTAMS (Any other variety).—*Cocks* —1, Miss Crawford. 2, T. P. Wood, jun., Boythorpe House, near Chesterfield. 3, W. B. Etches.

DUCKS (White Aylesbury).—1 and 4, Mrs. Seamons. 2, Mrs. Burrell. 3, J. K. Fowler. *hc*, Mrs. Seamons; H. Jones; J. K. Fowler. *c*, Countess of Dartmouth; H. Jones; Mrs. Burrell.

DUCKS (Rouen).—1, Cup, and 4, T. Statter. 2, A. Dickinson, Whitehaven. 3, J. Anderson. 5, S. Shaw. 6, L. Patton. *hc*, L. Patton; F. Parlett, Chelmsford; J. Anderson; S. H. Stott, Rochdale; J. K. Fowler; Gunson & Jefferson; C. Butler, Castle Bromwich; J. Fox. *c*, F. W. Zurhorst; J. Anderson.

DUCKS (Black East Indian).—1 and 3, Mrs. Hayne, Dorchester. 2, S. Burn, Whitby, Yorkshire. *hc*, Major F. D. L. Smith, Hales Owen; J. M. Kilvert. *c*, Rev. W. Serjeantson; Miss Clifton, Whittington, Worcester; S. Burn.

DUCKS (Any other variety).—1, S. Burn. 2, H. Mapplebeck. *hc*, H. Savile; T. C. Harrison; M. Leno; C. Homfray. *c*, Rev. W. Sergeantson.

GEESE (White).—1, Rev. G. Hustler. 2, Mrs. Seamons. *hc*, T. Statter; C. Bamford, Impington Hall, near Cambridge. *Goslings*, — 1, Mrs. Seamons, Aylesbury. 2, S. H. Stott. *hc*, Rev. G. Hustler, Stillingfleet Vicarage, York; Mrs. Seamons; J. Lycett, Stafford.

GEESE (Grey and Mottled).—1, C. Bamford. 2, J. K. Fowler. *hc*, Rev. G. Hustler; J. Lycett; H. Crossley; W. Lort, King's Norton, near Birmingham. *c*, Right Hon. Lord Wenlock, Yorkshire. *Goslings.*—1, Mrs. Seamons. 2, J. K. Fowler. *hc*, Rev. G. Hustler; S. H. Stott; J. Lycett. *c*, Lord Wenlock; W. Cox, Brailsford Hall, Derby.

TURKEYS.—'Old birds).—*Cocks.*—1, F. Lythall, Banbury. 2, T. J. Harrison, Kendal, Westmoreland. *hc*, Hon. Mrs. Colvile, Lullington, Burton-on-Trent; Rev. N. J. Ridley, Newbury; C. Bamford; Mrs. Guy, Eaton, Grantham; J. Fox, Cumberland; W. Sanday, Ratcliffe; W. Winterton, Hinckley; L. Patton. *c*, Rev H. G. Baily, Swindon; J. Fox. *Hens.*—1, W. Sanday. 2, F. Lythall. *hc*, Mrs. Guy, Eaton, Grantham; W. Winterton. *c*, L. Patton; Rev. H. G. Baily.

TURKEYS (Young Birds).—*Cocks.*—1, L. Patton. 2, Rev. T. Fellowes, Honningham, Norwich. *hc*, Mrs. Guy; F. Lythall; W. Wilkes, Wolvey; Hinckley, Leicestershire; Rev. G. Oilbert, Claxton, Norwich; W. Sanday; L. Patton. *Hens*—1, S. H. Stott. 2, L. Patton. *hc*, Rev. T. L. Fellowes, Mrs. Guy; W. Winterton; L. Patton. *c*, F. Lythall.

PIGEONS.

TUMBLERS (Almond).—1 and 3, R. Fulton, Deptford, London. 2, J. Ford, London.

CARRIER (Black). — *Cocks.* — 1, E. Horner, Harewood, Leeds. 2, T. Colley, Sheffield. *hc*, J. Thompson, Bingley, Yorkshire. *c*, F. Crossley, South House, Elland, Yorkshire; R. Fulton. *Hens.*—1 and 2, R. Fulton. *hc*, J. C. Ord, Pimlico, London; F. Crossley.

CARRIER (Dun).—*Cocks.*—1, J. Hawley, Bingley, Yorkshire. 2, J. C. Ord. *hc*, F. Crossley. *Hens.*—1, J. Hawley. 2, F. Crossley. *vhc*, J. Thompson.

CARRIER (Any other colour).—*Cocks.*—1, R. Fulton. *hc*, J. C. Ord. *Hens.*—1, H. A. Yardley, Edgbaston, Birmingham. *c*, J. C. Ord.

POUTER (Red).—*Cocks.*—1, P. H. Jones, Fulham, London. 2, R. Fulton. *c*, J. Barber, Kettering. *Hens.*—1, F. Gresham, Shefford, Beds. 2, G. Sturgess, Leicester. *c*, A. H. Stewart, Birmingham.

POUTER (Blue).—*Cocks.*—1 and Cup, E. Horner. 2, F. Gresham. *hc*, R. Fulton; W. Gamon, Chester. *Hens.*—1 and *hc*, R. Fulton. 2, F. Gresham.

POUTER (Black).—*Cocks.*—1, F. Gresham. 2, A. H. Stewart. *hc*, R. Fulton. *Hens.*—1, A. H. Stewart. 2, R. Fulton.

POUTER (White).—*Cocks.*—1, Mrs. Ladd, Calne, Wilts. 2, W. Harvey,

Sheffield. *hc*, G. Sturgess; R. Fulton. *Hens.*—1, R. Fulton. 2, W. R. Rose, Brausley Hall, near Kettering. *hc*, G. Sturgess; R. Fulton.

Pouter (Any other colour).—*Cocks.*—1, W. R. Rose. 2, R. Fulton. *Hens*—1, W. R. Rose. 2, R. Fulton. *hc*, A. H. Stewart.

Balds or Beards.—1, R. Fulton. 2, W. H. C. Oates, Beathorpe, Newark. 3, G. South, London. *hc*, W. Cheyce, Sibson, near Atherstone, Warwickshire; G. South. *c*, W Cheyce.

Tumblers (Short-faced).—1, J. Fielding, jun., Lark Mills House, Rochdale. 2 and *hc*, R. Fulton. *vhc*, F. Crossley. *c*, J. Ford, London.

Tumblers (Any other variety).—1 and *hc*, J. Hawley. 2, E. Horner.

Runts.—1, Cup, and 2, T. D. Green, Saffron Walden, Essex.

Jacobins (Red or Yellow).—1 and 2, J. Williams, Manchester. *hc*, R. Fulton; E. E. M. Royds, Greenhill, Rochdale; S. Shaw, Stainland, Halifax; O. South.

Jacobins (Any other colour).—1 and *hc*, E. E. M. Royds. 2, J. Williams.

Fantails (White).—1 and 2, C. Bulpin, Riverside, Bridgwater, Somerset. 3, H. Yardley. *hc*, J. J. Bradley, Birmingham; T. C. & E. Newbitt, Epworth, Lincolnshire; C. Bulpin.

Fantails (Any other colour).—1, F. Graham, South Birkenhead. 2, W. Cheyce, Sibson, near Atherstone. *hc*, H. Yardley.

Trumpeters (Mottled).—1, S. Shaw, Stainland, Halifax. 2, W. Harvey. *hc*, J. Firth, jun., Dewsbury. *c*, S. A. Taylor, Four Oaks, Sutton Coldfield.

Trumpeters (Any other colour).—1, J. Firth, jun. 2, W. H. C. Oates. *hc*, W. Gamoo, Hoole Cottage, Chester.

Owls (Foreign).—1, F. Crossley. 2, J. Fielding, jun. *hc*, S. Shaw.

Owls (English).—1, J. Edge, Birmingham. 2, C. Bulpin. *hc*, Rev. F. Watson; C. Bulpin. *c*, J. Firth, jun.

Nuns.—1 and 3, W. Baukes, Runcorn, Cheshire, 2, C. Bulpin. *hc*, W. Croft, Killinghall, Ripley, Yorkshire. *c*, P. H. Jones.

Turbits (Red and Yellow).—1 and *hc*, S. Shaw. 2, E. Horner.

Turbits (Any other colour).—1, G. South. 2, W. Baukes. *hc*, J. Fielding, jun.; H. Yardley.

Barbs (Black).—1, R. Fulton. 2, S. Shaw. *vhc*, F. Crossley.

Barbs (Any other colour).—1 and 2 F. Crossley. *vhc*, J. Firth, jun.

Dragoons (Blue).—1, G. South. 2, J. Percivall, Peckham, London. *vhc*, F. Sale, Derby. *hc*, H. Yardley; J. Percivall. *c*, H. Yardley.

Dragoons (Red or Yellow).—1, G. South. 2, P. H. Jones. *hc*, J. Thompson.

Dragoons (Any other colour).—1, J. Percivall. 2, J. Edge. *hc*, W. Underwood, Birmingham. *c*, F. Sale.

Magpies—1, P. H. Jones. 2, J. Firth, jun. *hc*, E. Horner.

Antwerps (Chequered).—1, J. W Ludlow, Birmingham. 2, C. Bulpin.

Antwerps (Any other colour).—1, S. A. Taylor. 2, J. J. Bradley.

Archangels.—1, C. Bulpin. 2, F. Sale. *hc*, W. Underwood.

Swallows.—1, E. Horner. 2, J. Watts, King's Heath, near Birmingham.

Any other New or Distinct Variety.—1, H. Yardley. Extra 1, G. Sturgess, Leicester. 2, F. H. Paget, Birstall, Leicester. Extra 2, W. B. Tegetmeier, Finchley, London. 3, F. H. Paget. Extra 3, H. Draycott, Humberstone, near Leicester.

Judges.—*Poultry:* Rev. G. F. Hodgson, North Petherton, Bridgwater; Mr. G. J. Andrews, Dorchester; Mr. John Baily, Mount Street, Grosvenor Square, London; Mr. James Dixon, North Park, Clayton, Bradford; Mr. E. Hewitt, Sparkbrook, Birmingham; Mr. R. Teebay, Fulwood, near Preston; Mr. J. H. Smith, Skelton Grange, York; Mr. R. Woods, Osberton, Worksop; Mr. E. Lowe, Comberford, Tamworth. *Pigeons:* Mr. Harrison Weir, 9, Lyndhurst Road, Peckham, London; Mr. T. J. Cottle, Pulteney Villa, Cheltenham; Mr. F. Esquilant, 4, Effra Road, Brixton, London; Mr. T. Ridpeth, Outwood Hall, Handforth, Manchester.

OAKHAM POULTRY AND PIGEON SHOW.

This meeting, held on the 24th and 25th of November, proved an unusually successful one, not a single hitch of any kind occurring, and the promptitude of action on the part of the Committee was itself perfection. The whole of the poultry, as well as the Pigeons, were contained in an excellent tent 200 feet long by 40 feet wide, an abundance of gas being laid on; and every attention was paid to the feeding, &c., of the birds.

Of Grey *Dorkings* the classes were exceedingly large, the silver cup for the best pen of this breed being awarded to a first-class pair of hens belonging to Mr. George Clarke, of Long Sutton. The silver cup for the best pen of a multiplicity of different breeds, to be entered expressly for the prize, which was given by the Earl of Gainsborough, was taken by a splendid pen of Brown Reds in a most spirited competition, Mrs. Fludyer, of Ayston Hall, being the winner. There were some very good Black *Spanish* shown, though the bulk of them were scarcely in full plumage. The winners of the silver cup, it seems, were entered in the catalogue at the low price of 30*s.*, being quite a novelty for good birds in these days. *Cochins* were exceedingly good. Mr. Taylor, of Manchester, was the principal winner. As regards *Game*, the pens shown by Mr. Mathews, of Stowmarket, had almost their own way. Mr. Jeffries, of Ipswich, was equally successful with Game *Bantams*. Mrs. Seamons, of Aylesbury, took both the silver cups for *Geese* and *Ducks* with uncommonly good birds, and in heavy classes. *Hamburghs* were in great force, and the cup went to a pen of Golden-spangled. A great variety of cross-bred fowls were shown in the class devoted to them. The produce of Light Brahmas with Grey Dorkings proved the best in all instances for table purposes. A cup was also given in the Selling class, and the Partridge Cochins were successful, the second prize going to Spanish.

The *Pigeons* consisted of large and excellent classes, but many of the best pens, detained at Peterborough, arrived long after the awards were completed—in fact, after nightfall had set in. Many fowls, also, were thrown out from being too late.

The arrangements of the Oakham Committee were for Mr. Joseph Hindson, of Liv and Mr. Hewitt, of Birmingham, to act as Judges; but unfortunately at the last moment a telegram announced the severe indisposition of Mr. Hindson, and consequently the whole of the duty devolved on Mr. Edward Hewitt.

Dorkings.—*hc*, G. H. Finch, M.P., Oakham. *c*, Mrs. W. Fryer, Uppingham; — Fowler, Willingham; C. Speed, Oakham.

Dorkings (Coloured).—*Cock.*—1, N. Savile, Rufford Abbey, Ollerton, Nottingham. 2, H. Warner, Loughborough. *hc*, R. Wood, Clapton, Thrapstone; J. Longland, Grendon, Northampton; D. C. Campbell, M.D. County Asylum, Brentwood, Essex; Marchioness of Exeter, Burghley House; H. Warner; J. Hornsby, Grantham; J. M. Wellington, Oakham. *c*, H. Yardley, Market Hall, Birmingham. *Hens or Pullets.*—1, Cup, and *c*, G. Clarke, Long Sutton. 2, R. Wood, Clapton, Thrapstone. *hc*, R. Wood; N. Savile; J. Hornsby, Castlegate House, Grantham; Mrs. Brackenbury, Thorpe Hall Farm, Downham, Norfolk; D. C. Campbell, M.D. *c*, O. Clarke.

Dorkings (Silver-Grey).—*Hens or Pullets*—1, Marchioness of Exeter. 2, W. Fowler, Manton, Uppingham. *hc*, D. C. Campbell, M.D.

Dorkings (White).—*Cock.*—1, Marchioness of Exeter. 2, O. E. Cresswell, Hanworth Rectory, Hounslow. *hc*, Mrs. Syson, Empingham, Stamford. *c*, Mrs. Syson; Marchioness of Exeter. *Hens or Pullets.*—1 and 2, Mrs. Syson. *hc*, Mrs. Syson; Marchioness of Exeter.

Spanish (Black).—1 and Cup, J. Stephens, Walsall. 2, Miss Collingwood, Peterborough. *hc*, G. Saunders, Melton Mowbray. *Chickens.*—1, F. James, Peckham. 2, J. Laming, Cowburn, Spalding. *hc*, W. R. Boll, Newport Pagnell; J. Stephens, Walsall. *c*, J. D. Hustwayte, Nottingham.

Cochin-China (Cinnamon, Buff, or Partridge).—*Cock.*—1, W. A. Taylor, Manchester. 2, H. V. Story, Lockington Hall, Derby. *hc*, J. Longland, Grendon; R. W. Smith, March; H. Lingwood, Needham Market; J. Stephens; T. H. Readman, Whitby. *c*, H. V. Story; J. Longland; — Godfrey, Hammersmith; J. Barber, Kettering; W. A. Taylor. *Hens or Pullets.*—1, Cup, and 2, W. A. Taylor. *hc*, H. V. Story; T. H. Derry, Gedney. Wisbeach. *c*, G. H. Finch, M.P.; Mrs. Woodcock, Rearsby House, Leicester; J. Stephens.

Cochin-China (Black or White).—*Cock.*—1 and 2, Mrs. Williamson. Queniborough Hall, Leicester. *hc*, H. J. Godfrey; Mrs. Williamson. *Hens or Pullets.*—1, Mrs. Williamson. 2, H. H. Eletsoe, Barowell, Oundle. *hc*, M. Kew, Market Overton, Oakham.

Brahma Pootra.—*Cock.*—1, Mrs. Woodcock. 2, Mrs. Williamson. *hc*, H. Lingwood, Needham Market, Suffolk. *c*, Mrs. Burrell, Stoke Park, Ipswich. *Hens or Pullets.*—1, Mrs. Woodcock. 2, H. Lingwood.

Hamburgh (Silver-spangled).—1, J. Laming. 2, A. Fairbourn, Todmorden. *hc*, N. Marler, Denton, Manchester. *c*, B. Jarvis, Mansfield.

Hamburgh (Silver-pencilled).—1, J. Laming. 2, A. Houghton, Ashfordby, Melton Mowbray.

Hamburgh (Gold-spangled).—1 and Cup, T. May, Wolverhampton. 2, J. Laming. *hc*, S. & R. Ashton, Mottram; N. Marler.

Hamburgh (Gold-pencilled).—1, J. Laming. 2, W. Tickner, Ipswich, Suffolk.

Game.—Cup, Mrs. Fludyer, Uppingham. *c*, Exors. of J. Hawley.

Game (Red and other dark colours).—*Cock.*—1 and Cup, S. Matthews, Stowmarket. 2, Mrs. Fludyer. *hc*, T. Whittaker, Melton Mowbray; R. Hall, Cambridge; H. Warner; B. Jarvis, Apsley Cottage, Mansfield. *c*, E. Winwood, The Grove, Worcester; T. Garton, Oakham; R. L. Healey; J. Eaton, Vine Cottage, Farnsfield, Notts. *Hens or Pullets.*—1, S. Mathews, Stowmarket, Suffolk. 2, T. Garton, Oakham. *hc*, R. Hall; Mrs. Lowther, Barleythorpe Hall; R. Swift, Southwell, Notts; B. Jarvis, Apsley Cottage, Mansfield; R. L. Healey; W. Bradley, Worcester.

Game (Piles, and light colours).—*Cock.*—1, S. Mathews. 2, E. Winwood, *hc*, W. Smith, jun., Easthorpe, Bottesford; G. Henfrey, Mapleback, Newark. *c*, M. Brown, Melton Mowbray. *Hens and Pullets.*—1, E. Winwood. 2, W. H. Mitchell, Moseley, Birmingham. *hc*, S. Deacon, Polebrook Hall, Oundle.

Bantams (White, clean legs).—1, S. & R. Ashton. 2, H. Draycott, Humberstone, Leicester. *c*, H. L. Bradshaw, Wakerley, Northampton.

Bantams (Black, clean legs).—1, Cup, and 2, H. Draycott. *hc*, A. Storrar; W. A. Taylor. *c*, S. & R. Ashton.

Bantams (Silver-laced).—1, G. H. Finch, M.P., Oakham.

Bantams (Any other distinct variety).—1, J. Adkin, jun., Walsall. *hc*, H. Warner; Mrs. Woodcock. *c*, H. Draycott.

Game Bantams.—*Cock.*—1 and 2, W. B. Jeffries, Ipswich. *hc*, M. Kew; H. Hedley; Miss S. E. Wellington; A. Storrar, Peterborough. *c*, H. Warner, Loughborough; T. Dyson, Halifax; J. Eaton, Farnsfield, Notts. *Hens or Pullets.*—1 and Cup, W. B. Jeffries. 2, J. Eaton. *hc*, S. Deacon, Oundle; M. Kew; H. L. Bradshaw, Wakerley; Miss S. E. Wellington.

Polands (Any colour).—Prize, G. W. Boothby, Louth.

Crossbred.—*Chickens.*—1, J. Longland, Grendon, Notts. 2, Miss S. Wellington. *hc*, H. Dowsett, Pleshey, near Chelmsford; Miss S. E. Wellington, Oakham. *c*, M. Kew; N. Savile; Mrs. A. Blackwood, Oakham.

Any other Distinct Variety.—1, W. Dring, Faversham, Kent. 2, Right Hon. Lady Berners, Keythorpe Hall.

Turkeys.—*hc*, Mrs. Lowther; M. Key, Oakham. *Cock.*—1, G. R. Pearson, Witham Common, Colsterworth. 2, Mrs. A. Guy, Eaton, Grantham. *hc*, Marchioness of Exeter; M. Kew, Market Overton, Oakham; T. N. Beasley, Northampton; Mrs. Berridge, Burley-on-the-Hill, Oakham. *Hens.*—1 and Cup, G. R. Pearson. 2, M. Kew. *hc*, M. Kew; Mrs. A. Guy. *c*, L. Patton.

Ducks.—*hc*, G. H. Finch, M.P., Oakham; Mrs. Lowther.

Ducks (White Aylesbury).—1 and Cup, Mrs. Seamons, Aylesbury. 2, J. Hornby, Grantham. *hc*, W. Carver & Sons, Ingarsby, Leicester; Mrs. Seamons. *c*, S. Deacon, Oundle; M. Kew; G. H. Finch, M.P.; H. V. Story.

Ducks (Rouen).—1 and 2, L. Patton. *hc*, H. Warner, The Elms, Loughborough; H. Yardley, Market Hall, Birmingham; R. Swift, Southwell.

Ducks (Any other variety).—1, M. Kew (Grey Calls). *hc*, M. Kew (Buenos Ayrean); Mrs. Lowther, Barleythorpe Hall (Buenos Ayrean); H. V. Story, Derby (White Muscovy).

Ducks (Crossbred or Common).—*Ducklings.*—1 and 2, Mrs. Berridge.

Geese (White).—Prize, J. Garton, Cotes, Loughborough. *hc*, Mrs. Berridge; N. Savile, Rufford Abbey, Ollerton. *Goslings.*—1 and Cup, Mrs. Seamons, Hartwell, Aylesbury. *hc*, T. N. Beasley; Mrs. Berridge; J. Christian, Oakham.

Geese (Grey).—Prize, Rev. C. H. Lucas, Edithweston, Stamford. *hc*, Mrs. E. Goodliffe, Stilton, Hunts; M. Kew. *Goslings.*—1, M. Woodroffe, Stanford, Loughborough. *hc*, Mrs. Seamons; M. Kew.

Selling Class.—1 and Cup, T. M. Derry, Gedney (Partridge Cochins). 2, J. Stephens (Black Spanish). *hc*, W. A. Taylor, Manchester; M. Kew; W. Dring, Faversham, Kent; Mrs. Berridge; G. Clarke, Long Sutton;

A. B. Brackenbury, Downham Market; H. Chappell, Oakham; J. Stephens, Walsall. *c*, S. Deacon, Oundle; G. Clarke; G. H. Finch, M.P.; Mrs. Brackenbury; J. Wright, Melton Mowbray.

PIGEONS.

Tumblers.—1, J. H. Ivimy, Lingfield, East Grinstead, Sussex. 2, H. Brown, Walkley, Sheffield. *c*, J. McArdale, Kensington, Liverpool; H. Yardley.

Carriers.—1, E. Walker, Leicester. 2, J. C. Ord, London. *c*, H. Yardley; H. Hedley, Thurmaston, Leicester.

Pouters.—1, E. Walker. 2, R. F. Payling, Peterborough. *hc*, R. F. Payling; H. Draycott, Hamberstone. *c*, H. Brown, Walkley, Sheffield.

Jacobins.—1, H. Yardley. 2, J. C. Ord. *hc*, H. Hedley. *c*, J. C. Marshall, Peterborough.

Fantails.—1, J. D. Loversidge, Newark-on-Trent. 2, F. H. Paget, Birstall, Leicester. *hc*, H. Yardley.

Trumpeters.—1, J. C. Ord. 2, E. Sheerman, Chelmsford, Essex. *hc*, Mrs. Woodcock, Leicester. *c*, J. H. Paget.

Nuns.—1, H. Yardley. 2, W. Croft.

Turbits.—1, H. Yardley. 2, J. C. Ord. *hc* and *c*, F. H. Paget.

Runts.—1 and 2, H. Yardley.

Any other New or Distinct Variety.—1, J. H. Ivimy. 2, H. Draycott, Hamberstone, Leicester. *hc*, J. McArdale; H. Hedley; H. Draycott; J. C. Marshall, Peterborough; J. C. Ord. *c*, J. McArdale; H. Hedley; F. H. Paget; E. Brown, Sheffield.

CHIPPENHAM POULTRY SHOW.

All the arrangements were excellent, and most of the poultry exhibited were of very superior quality. The Grey *Dorkings* were better than have yet been shown in this neighbourhood; and the *Game* fowls merited our highest praise. The *Polands* were of great merit, particularly the Silver-spangled. The *Hamburgh* classes were also well filled. Of *Brahmas* there was only a very small entry, and those not what could be wished. The Aylesbury and Rouen *Ducks* were praiseworthy, and the *Turkeys* and *Geese* would have been a great credit to any show. A hybrid, bred between the wild English Pheasant and a common domestic fowl, was a good specimen, and proved very attractive. The weather was exceedingly fine, and the attendance unusually large.

Dorkings.—1, Miss Millward, Newton St. Loe. 2, G. Hanks, Malmesbury. *c*, J. Kingdon, Calne; Rev. J. Hoysted, Bradenstoke.

Spanish.—1, Tonkin & Tuckey, Bristol. 2, A. Heath, Calne.

Game (Black-breasted and other Reds).—1 and 2, H. Stagg, Netheravon.

Game (Any other variety).—1 and 2, G. Sainsbury, Devizes. *c*, G. Hanks.

Cochins.—1, Miss Millward. 2, J. W. W. Hulbert, Chippenham.

Brahmas.—1, J. Kingdon. 2 and *c*, W. Hanks, Somerford. *hc*, Rev. J. Hoysted.

Hamburghs (Gold or Silver-pencilled).—1, T. Sealy, Little Somerford. 2, J. Orlidge, Chippenham. *hc*, J. W. W. Hulbert; — Thompson, Calne.

Hamburghs (Gold or Silver-spangled).—1, J. W. W. Hulbert. 2, J. S. Maggs, Tetbury.

Polands.—1 and 2, J. Hinton, Warminster. *c*, R. C. Forster, Freshford.

Game Bantams.—1, E. Cambridge, Bristol. 2, E. C. Owen, Shrivenham.

Bantams (Any other variety).—1, E. Cambridge. 2, N. J. Clark, Bristol.

Any other Distinct Breed.—1, Wyndham & Ward, Salisbury. 2, J. Hinton. *hc*, R. C. Forster.

Cross-Breeds (Distinct).—1, G. S. Sainsbury. 2, — Vick, Chippenham.

Turkeys.—1, Miss Milward. 2, S. W. Stokes, Heddington.

Geese.—1, J. Baker, Allington. 2, G. Hanks. *hc*, H. Say, Lacock.

Ducks (Rouen).—1, G. M. Hulbert. 2, G. S. Sainsbury. *hc*, G. Hanks.

Ducks (Aylesbury).—1, J. S. Maggs. 2 and *hc*, G. Hanks.

Ducks (Any other variety).—1, H. Brinkworth. 2, Rev. R. H. Mullens. *c*, J. Goulter.

Sweepstakes for Game Cock.—1 and 2, H. Stagg. 3, G. S. Sainsbury.

Extra Stock.—Extra Prize, R. J. Butler (Peacock). *c*, F. W. Dowding, Chippenham (Mule).

The Judge was Edward Hewitt, Esq., Sparkbrook, Birmingham.

JOHNSTONE POULTRY AND PIGEON SHOW.

(*From a Correspondent.*)

Last year the Exhibition was held in an empty mill, which served the purpose extremely well, but this year I was astouished at the beautiful hall in which the Show of November 19th took place.

The first on the catalogue was the *Spanish*, and certainly this class was well represented, the first-prize pen being first-rate. *Dorkings* formed a good class; the first-prize cock was good in every respect, except in weight, but this will soon be made up. *Brahma Pootras* or *Cochin-Chinas* were very good, but in my estimation the Brahmas ought not to have been first, but the Cochins, which were in every way better, and I would advise the Committee to make a class for each. The Black or Brown Red *Game* were excellent, and the awards were very correct. The first-prize cock (Duckwing) was a powerful bird, good in limb, but rather light in body. The *Scotch Greys* were an excellent class, but I am sorry to say that some of the birds were debarred from receiving awards because their feathers were improved artificially. Golden-spangled *Hamburghs* were numerous and good. The Golden-pencilled Hamburghs were not behind the Spangled Hamburghs; I consider the third-prize pen should have stood higher. Silver-spangled Hamburghs were good, and the judgments not out of place. Silver-pencilled Hamburghs were not so numerous as the other classes, but the prize birds were really good. Game *Bantams*, as is usual at almost every show, were very numerous, perhaps more than thirty pens being exhibited. The judgment was very creditable in this class, and the first-prize pen was nearly perfect. In Bantams, any other colour, Sebrights gained the day, but I consider the Black Bantams were more perfect. In the "Variety" class a beautiful pen of Malays and Sultans was overlooked altogether, though the prize Polands were very good. The Rouen and Aylesbury drakes and *Ducks* were first-class. The Selling class consisted of different varieties, and Pencilled Hamburghs seemed to be the taste of the Judges.

The *Pigeons* on the whole were very good, but I am sorry to say that the "dressing" was rather glaring. Blue Pouters were lengthy and good-coloured; Black Pouters were good, but were overdone in polishing; White Pouters were good, but entirely overlooked. It is seldom so many good Carriers are exhibited at a show like Johnstone. A good many of the Short-faced Tumblers were helped by the "brush," but were nevertheless good. Barbs were first-class and numerous, and the awards were rightly given. Fantails were of a superior kind. Jacobins were good and well judged. Common Tumblers and common Pigeons were of an ordinary quality. In the Variety class a beautiful pair of White Owls was awarded the first prize, and also an eight-day timepiece, as being the best pen from class 7 to class 12. Black Pouters gained the other timepiece in the other division of the Pigeons; the Black Pouters belonged to J. Millar, Glasgow, and the Owls to Mr. J. Fielding, Rochdale. In the poultry department Miss Hodgart's (Paisley) Spanish gained a timepiece, and J. Stewart's (Barrhead) gained another. The silver bread-basket was gained by Bellingham & Gill, for the best pair of hens; the second prize (a silver sugar-bowl) was gained by a pair of Dorking hens belonging to Mr. J. Gray, Airdrie.

Spanish.—1, A. Hodgart, Paisley. 2, H. Wilkinson, Earby, Skipton. Extra 2, A. Yuil, Calderbank, Airdrie.

Dorkings.—1, J. Gray, Airdrie. 2 and 3, A. J. Muttor, Kilmarnock.

Brahma Pootras or Cochin-Chinas.—1, A. Grant, Glentyan Mills (Brahma). 2, J. Boyd, Paisley (Brahma). 3, T. H. Reedman, Whitby (Cochin).

Game (Black or Brown Red).—1, J. Waddell, Acrehead, Dumfries. 2, R. Alexander, Bridge-of-Weir. 3, J. Logan, East Shields, Carnwarth.

Game (Any other colour).—1, R. Andrew, Grahamston. 2, J. M'Indoe, Barrhead. 3, J. Waddell.

Scotch Greys.—1, R. Blair. 2, J. Taylor, Johnstone. 3, M. M'Donald, Johnstone.

Hamburghs (Golden-spangled).—1 and 3, J. Jardine, Kilmarnock. 2, R. Tyson, Longtown, Carlisle.

Hamburghs (Golden-pencilled).—1, R. Clark, Johnstone. 2, J. Howe, Paisley. 3, J. Mair, Craigie, Kilmarnock.

Hamburghs (Silver-spangled).—1, J. Stewart, South Arthurlie, Earrhead. 2, R. Bruce, Busby. 3, J. Moodie, Paisley.

Hamburghs (Silver-pencilled).—1, H. Arndle, Stonefield, Paisley. 2, R. T. Gemmell, Glasgow. 3, H. Pickles, jun., Earby.

Game Bantams.—1, J. Waddell. 2, J. Gow, Kilmarnock. 3, B. Muir, Knox, Kilbirnie.

Bantams (Any other variety).—1, W. Morris, Linside, Paisley (White). 2, H. Pickles, jun. (Black). 3, R. Stirrat (White).

Any other Variety.—1, H. Pickles, jun. 2, W. M'Kenzie, Paisley (Polands). 3, J. Allan, Kilbirnie (Crêve-Cœurs).

Ducks (Aylesbury).—1 and 2, A. Robertson, Kilmarnock. 3, Z. H. Heys, Barrhead.

Ducks (Any other variety).—1, A. Robertson. 2, A. Grant, Kilbarchan. 3, J. Logan, East Shields, Carnwath.

Selling Class (Any breed).—1, C. Martin, Barrhead. 2, A. Mitchell Paisley. 3, H. Wilkinson.

Any Breed.—*Hens.*—1, Bellingham & Gill, Woodfield, Burnley. 2, J Gray.

Extra Prizes.—Miss Hodgart (Spanish); J. Stewart, South Arthurlie, Barrhead (Silver-spangled Hamburghs).

PIGEONS.

Pouters (Blue).—1, J. Millar, Glasgow. 2, R. Arbuckle, Parkhead. 3, H. Thomson, Glasgow.

Pouters (Any other colour).—1 and 3, J. Millar, Glasgow. 2, J. Mitchell, Glasgow.

Carriers.—1, J. Millar. 2 and 3, J. Muir, Glasgow.

Tumblers (Short-faced).—1 and 2, J. Muir. 3, J. Millar.

Barbs.—1 and 3, J. Muir. 2, J. Millar.

Fantails.—1, J. Sharp, jun., Johnstone. 2, J. Galt, Kilbirnie. 3, W. Jacobins.—1 and 3, P. Donald, Johnstone. 2, J. Waddell.

Tumblers (Common).—1 and 2, D. K. M'Kay, Glasgow. 3, P. Donald.

Common.—1, J. Lamont, Kilwinning. 2, R. Stirrat, Dalry. 3, A. Walker, Dalry.

Magpies and Nuns.—1, J. G. Orr, Beith. 2 and 3, P. Donald.

Any other Distinct Breed.—1, J. Fielding, Rochdale. 2, G. White, Ladyburn. 3, P. Donald.

Selling Class (Any breed).—1, J. Galt, Maybole. 2, P. Donald. 3, J. Smith, Johnstone.

Extra Prizes.—J. Millar (Black Pouters); J. Fielding (White Owls).

The Judges were:—*Poultry:* A. Paterson, Esq., Airdrie; J. M'Innes, Esq., Paisley; J. H. M'Nab, Esq., Barrhead; T. Short, Esq., Partick. *Pigeons:* J. Hnie, Esq., Glasgow; and J. H. Frame, Esq., Carluke.

BEE FARMING IN 1869.

In many counties of England the honey harvest has been satisfactory this year. The yield has been greater than for some years previous. Last year bees were remarkably loath to swarm—comparatively few swarms were obtained; whereas this year they swarmed freely, often before the hives were well filled. Last year they clustered about their doors for weeks and months without swarming; this year they sent off colonies without clustering or hesitation. No explanation can be given of these things; their reasons or causes are deeper than the ken of mortals.

My balance sheet last autumn left me with a profit of 21*s.* per hive, or thereabouts, and in possession of twenty-eight stock hives. These we valued at 23*s.* each, or 7*s.* less than the tip-top price. The winter being mild, they kept their bees well—that is to say, they were in good condition in February of the present year. As my garden is too near the big city of Manchester for bees to gather much honey, I took twenty hives to cottage and market gardens three or four miles in the country. Of course, I pay rent, and I am glad to do so, for there my bees have richer pasture; but the expense of taking them to and from these farms is considerable. My expenses will overtop those of most bee-keepers. This year my expenses are unusually heavy, amounting to more than 10*s.* per hive. Two of the hives in the country I found in May had queens which had never been mated, and were, therefore, useless. Thus my number was reduced to twenty-six. Of these, two never swarmed; the rest yielded thirty-three swarms, three of which were lost for want of hiving. After swarming, the queens of two hives were lost on their marriage tour, thus adding to the list of my misfortunes.

Owing to the prevalence of easterly winds, the season, on the whole, was not a favourable one for the accumulation of honey in this locality. These easterly winds either hinder the secretion of honey in flowers, or dry it up. Still honey in moderate quantity was gathered, the roar of contentment was kept up, great quantities of brood were hatched, the bees were always prepared to do more work than the weather permitted. At the close of the season my best first swarms ranged in weight from 70 lbs. to 80 lbs. each, the second swarms from 30 lbs. to 40 lbs., and the stocks or parent hives, from 50 lbs. to 70 lbs. each. These weights indicate considerable stores of honey, and large profits. But when we commenced to take the honey to supply an order for 500 lbs., we found much of it discoloured; and the discoloured honey was so mixed with the good and pure, that we could not take the one from the other without great loss. We did not hesitate about declining to supply the gentleman who had ordered 500 lbs., for we felt sure the honey would not please either him or his customers; but the difficulty was, what to do with the heaviest hives. We resolved to offer them for sale at a price less than the value of the honey in them. Hence, we sold some, and kept far more for another year than we had intended to keep. There are forty-two hives kept as stock for another year. Many of them are large and good, with ample stores of honey; but owing to the misfortune of having to sell some of the bees with their honey, they have not received swarms and half swarms in the usual way practised here. Still, I value them at 23*s.* each. If I had an extra swarm to put into each, they would have been worth 30*s.* each, and second to none.

How did the honey become discoloured? The sycamore, lime, and oak trees in this neighbourhood were covered with a glittering substance produced by insects, which ignorant people call honeydew. When flowers are scarce, bees work on these shining leaves, and in this way honey becomes damaged. Two years ago, much English honey was dark and unsaleable.

Expenses.	£	s.	d.
New hives, boards, and honey glasses	4	0	0
Feeding	1	4	0
Rent	4	0	0
Carriage	4	0	0
	13	4	0

Income.	£	s.	d.
Hives sold	12	8	0
Honey and honeycomb	15	0	0
Increase of stock	16	10	0
Total	43	18	0
Deduct expenses	13	4	0
Profit	30	14	0

When writing the above, a note came from my friends at Carluke, in Lanarkshire, where bee-keeping is a source of great profit. The writer says:—

"Carluke, October 5th, 1869.

"My dear old Friend,—I beg to be excused for not replying to your note sooner, but I waited till I got my bees home from the moors, and the honey taken from them. I jarred it all up yesterday, and find that out of ten hives we have taken upwards of 410 lbs. The heaviest hive we had weighed 120½ lbs., two or three of them about 93 lbs, the rest from 60 lbs. to 70 lbs. We had three boxes of honeycomb also, which realised 27*s.* The above is the produce of six stales or stock hives. So you see the bees have done well with us this season. One hive, a second swarm 80 lbs. weight, was sold for £2 5*s.*—Yours truly, R. R."

These figures indicate £22 income from six hives; the expenses are not stated. His heaviest swarm was, as mentioned above, 120½ lbs.; the heaviest in the parish, 128 lbs. Last year the heaviest swarm was 168 lbs.; in 1866, 140 lbs.; and in 1864, 162 lbs. This year my aunt, aged 78, a veteran bee-keeper of sixty years' standing, had 250 lbs. of honey from four stocks. A disease never before known in the parish has appeared in many hives this year. It has been described to me by several of the leading apiarians there. Much of the brood dies in the combs. It is not foul, for when the combs are taken out and broken, the brood—small, exceedingly small, bees—perfect in form, dead and dry, roll out in great numbers, like small peas, on the floor, I am quite unacquainted with this disease.— A. Pettigrew. *Rusholme, Manchester.*

Curiosities of Natural History.—A black Woodcock has been shot in Norfolk. A pied Thrush, white in the head, body, and throat, with brown wing and tail, has been captured near Chippenham. At Peckham, on November 9th, Sparrows were busy building. Do they anticipate a mild winter? The grey Phalarope has entered an appearance in Sussex in considerable numbers. The assumption by a sterile female Silver Pheasant of the male plumage is a remarkable phenomenon, not hitherto observed in this species. She was originally brown, but is now nearly all white, the long white feathers of the tail giving her entirely the appearance of a cock bird.—(*Exchange and Mart.*)

OUR LETTER BOX.

"Aliquis," we regret to hear, is incapacitated for writing at present, but he hopes to be able to notice his opponents next week.

Broken Crockery (*H. C. J.*).—If broken into very small fragments it might be useful where gravel could not be resorted to by fowls, but it is not possible that it could supersede the need of mortar or chalk for them, inasmuch as no common crockery contains lime.

Game Piles' Legs (*Nemo, Nantwich*).—There is no specified colour that is absolutely required by judges. We prefer white, but yellow and willow are admissible.

Black Hamburghs for Exhibition (*Black Hamburgh*).—Your diet will do; but do not overfeed the birds, and one week's confinement previous to the show would be quite enough. Certainly do not let them be relaxed in their bowels. Leave the pills alone.

Cross Between a Dorking and Guinea Fowl (*H. W.*).—We have seen the result of the cross you mention. The hybrid bird resembled the Guinea fowl in shape generally, and in its plumage; the head, feet, and flesh resembled the other parent.—B.

Brahma Pootra Vulture-hocked (*Subscriptum ab initio*).—If the red marks in your sketch represent the feathers the bird is decidedly vulture-hocked.

Fowls Waiting for Shipment (*G. G.*).—In keeping birds that are waiting for shipment, it is always advisable to put them as soon as possible in the pens in which they are to make the voyage, supposing you speak of one of considerable duration. In all breeds, with the exception of Game fowls, a pen of a cock and two or three hens may be sent in one pen or compartment. The food must be light and easy of digestion, and water but sparingly given.

Houdan's Wing Injured (*E. P. F.*).—Your Houdan, if it has lost a portion of its wing proper, would stand but little chance in competition. If, however, you have cut the plumage, the bird would most likely be disqualified as "marked."

Winter Food for Fowls (*Far West*).—We find no food answer so well as good barleymeal or ground oats made into stiff dough and given night and morning; a little maize or tailing wheat at mid-day. If extra feeding be required, a small quantity of thoroughly scalded tallow greaves may be mixed with the meal.

Game Fowl's Eyes Swollen (*A. B.*).—We should recommend for your fowls a thorough change of diet, and a course of castor oil, the heads frequently washed with vinegar and water, and we should put camphor in their drinking water. Baily's roup pills may be given with advantage.

Wing Disease in Pigeons (*Fox*).—Apply tincture of iodine, which you may obtain of any chemist, and he will, according to the strength he makes it, tell you how often it should be applied. In addition, attend in every way to the health of your bird.

Teaching a Parrakeet to Talk (*J. A.*).—If you want a bird to talk, you must teach it by talking to it, saying the same word over and over again, when the bird and you are alone. Parrakeets are, however, more pleasing to the eye than to the ear. Far from fluent, yet they please by their beauty, their graceful movements, and their affectionate disposition.

Driving Bees (*L. H.*).—The instructions for uniting bees by driving, given in "Bee-Keeping for the Many," do not embrace the removal of the supernumerary queen, as the bees will themselves usually settle this question in a satisfactory manner. A bee-veil and gloves had better be worn by a novice, although these are quite unnecessary when the operator is a skilled apiarian.

Cooking Cardoons (*Rev. W. H.*).—Cut them in pieces 6 inches long, and put them on a string; boil till tender, have ready a piece of butter in a pan, flour and fry them. They may also be fried in bundles and served as asparagus, boiled on a toast, and butter poured over. Another method is to cut them in pieces, take off the outside skin, and wash and scald them. Put them into a stewpan, add stock enough to cover them, boil till three parts done, and the liquor nearly reduced; then add a little bechamel, and stew them gently till done. Serve with sippets of fried bread round the dish, and the cardoons in the centre.

POULTRY MARKET.—December 1.

From observations taken near London during the last forty-two years, the average day temperature of the week is 46.5°; and its night temperature 33.4°. The greatest heat was 63°, on the 12th, 1841; and the lowest cold 13°, on the 9th, 1867. The greatest fall of rain was 1.24 inch.

HEATING BY HOT-WATER PIPES.

PERHAPS in the long list of horticultural means and appendages, none are so little understood as the theory and practice of heating by hot water, nor any of them surrounded by so much mystery; yet the subject is so simple, and requires so little time to master it, that no lady or gentleman should be ignorant on this point or liable to be imposed upon.

Very few indeed understand why the water circulates in the pipes, the prevalent idea being that the fire drives the water out of the boiler with great force. Such is not the case, the circulation of water is always comparatively weak. The force it possesses is only equivalent to the difference in weight between the ascending and descending column of water. Hot water is lighter than cold; therefore when the fire is applied to the boiler the water in it becomes hotter and lighter than that in the pipes attached to it, consequently it ascends, and its place is supplied by the water in the pipes, which is cold and heavier. The pipes being higher than the boiler, the water descends into it. This goes on till the whole of the water in the apparatus becomes comparatively warm. Of course the water is hottest in the boiler, hot in the flow pipe, and cooler in the return. What I mean by this is that the water is gradually cooled as it leaves the boiler by the heat being absorbed from it by the action of the air on the surface of the pipes. Thus the force of the current corresponds to the difference between the boiler and the return pipe in the temperature and specific gravity of the water. The force is easily calculated, but it would not be interesting to go into details of this kind; let it be sufficient to say I believe the average force in a 4-inch pipe as usually laid in a greenhouse is only equal to about one-third of an ounce. This tells us we must so place the pipes as to afford no resistance to the current—that is, we must have no sharp turns nor irregular depressions, especially in the return pipe, which should always have an even descending course.

When about to construct a warming apparatus, the first point is to decide upon the kind of pipes we shall use—that is, Should they be large or small? Small pipes become hot the quickest, present more heating surface in proportion to the water they contain, require less fuel, and become cold quicker than those of larger diameter. They are more portable, and far more expensive. Pipes of large diameter do not present so great a heating surface in proportion to their cubic contents, but they keep hot longer after the fire is out, and are cheaper, and perhaps more suitable to greenhouses.

To make this clear, a 4-inch pipe contains in each foot of length nearly 146 cubic inches of water, and presents about 144 inches of heating surface; a 2-inch pipe contains in each foot of length nearly 38 inches of water, and presents 72 inches of surface: therefore one row of 4 inch pipes gives off as much heat as two rows of 2-inch pipes, but contains nearly double the quantity of water and requires double the quantity of fuel to keep up the heat—that is, the two rows of 2-inch pipe are equal in warming power to the one row of 4-inch, and superior to it in economy.

Having decided on the diameter of the pipes, we next require to know the quantity we shall want to keep a certain house warm. This is done by proportioning the surface presented by the pipes to the surface presented by the glass; for so great is the cooling power of the glass that it puts the cubic contents of the house out of the calculation. Therefore we only require to know how much air a foot of glass will cool down from a certain temperature to a lower one, and the quantity of air a foot of heating surface will raise in temperature in the same (opposite) way. However, it would, I fear, make my paper too long if I were to go into this matter scientifically: so I will give a rule for calculating the quantity of pipes required to heat any building of the horticultural class.

Decide upon the heat you require in the house when the temperature of the external air is at the lowest point. The quantity of air to be warmed per minute is 1¼ cubic foot for each foot superficial of glass the house contains. When the quantity of air to be heated per minute has been decided upon, multiply 125 (the excess of the temperature of the pipe above that of the surrounding air), by the difference of the temperature at which it is proposed to keep the house above that of the external air, and divide this product by the difference between the temperature of the pipes and the proposed temperature of the house; then the quotient multiplied by the number of feet of air to be warmed, and this product divided by 222 (the number of feet of air raised 1° per minute by 1 foot of 4-inch pipe), will give the number of feet of 4-inch pipe required to produce the desired effect.

Now, we want to know how large a boiler we require to heat the water to supply the pipes. For each 50 feet of 4-inch pipe, the boiler must present one square foot of surface to the direct action of the fire: so if the house contains 200 feet of pipe, a boiler will be required that presents 4 feet of surface to the fire. Never count anything for the surface exposed to the action of flame upon the top of it, such as the top of any boiler, for the fire would never have power enough to boil water underneath it.

I have now stated enough to enable ladies or gentlemen to know which pipes will suit their purpose the best, how many feet of piping they will require, and the size of boiler necessary to heat the water. If they will only rely on their own judgment, and follow the teachings of science, they will not be so frequently disappointed in the warming of their horticultural houses.—John Woolfield, *Soho, Birmingham.*

GUERNSEY CHRYSANTHEMUMS.

Guernsey seedlings of this popular and useful flower—not that I personally like or admire it, considering it much overpraised—have become so well known to English shows, and have so good a place in Messrs Salter's list, that these brief notes of mine taken at an insular exhibition may add to the interest felt in them, Guernsey holding just now four

of the principal raisers. These four are named Smith, Davis, Pethers, and Clark. Strangely enough, Jersey has as yet produced nothing of value, so that possibly I may serve the cause of truth in vouching for this just discrimination. The initials of the raisers are added.

Of large-flowered varieties some of the best exhibited were, Lady Harding (C), of a delicate rose pink, a well-known show flower; Princess of Teck (P), pure white, of grand size, excellent for cut blooms; Princess of Wales (D), pearly white, delicate rose-lilac tints, of exquisite form in the florets; General Slade (S), Indian red, tipped purely and clearly with orange, and a very striking show flower; Guernsey Nugget (P), clear yellow with pink tinge, a full and distinct flower; Her Majesty (S), silvery blush, compact, and dwarf in habit; Gloria Mundi (C), brilliant golden yellow, somewhat like the well-known Jardin des Plantes, and a seedling from it, but earlier, being a great acquisition; Cherub (S), rosy, golden amber, a large well-shaped flower for cut blooms; Donald Beaton (S), dark orange red, a very beautiful show flower; Ossian (P), rose, very large, well-shaped, altogether a fine variety; Sir Stafford Carey (P), dark chestnut, edged with gold, very distinct and good; Mr. Gladstone (D), dark red chestnut, perfect shape, and a splendid show flower; Mrs. Cunningham, a sport from Queen of England; Mrs. Brunlees (S), delicate rose pink, of exquisite form, and having the merit of flowering late; Miss Marechaux (P), pure white, wide florets, and very good; Antonelli (S), orange salmon, large, and beautifully incurved; Lady Carey (S), rosy lilac, large, and extremely showy; Eve (S), pale primrose yellow, incurved, very perfect as a cut bloom.

A fine large specimen plant of Little Harry (S), of a bright golden hue, and of exquisite form of "petal"—indeed unsurpassable as such—was also exhibited. Christine and Golden Christine, were likewise very fine. The former, raised by Smith, is a fine large-flowered variety, of a rosy blush. Golden Christine is a sport from Christine.

The whole of these varieties, to which many more might be added, were produced in Guernsey, with the exception, I believe, of Golden Christine, and specimens of all were shown in various ways.

I may add that the show was not confined to Chrysanthemums, but the fruit was inferior. A basket of late American Peaches was sent from our orchard houses, being the only Peaches there. At Mr. Smith's, of the Caledonia Nursery—one of the Chrysanthemum raisers above mentioned—I also saw on November 27th a standard Maréchal Niel Rose, budded on a Manetti stock last July, having twenty-seven blooms on it. All the Roses on the Manetti in this nursery are budded on the principles laid down by Mr. Radclyffe. Not a sucker is to be seen. Climbing Devoniensis on a west wall was thriving. One of the island specialities, too, in the shape of bulbs, especially Gladioli, was well represented in this nursery. Guernsey can thus fairly claim a pre-eminence in Chrysanthemums, bulbs, Chaumontel Pears, and hurricanes. Jersey shares with us in the last three, but in the first is far behind.—T. C. Bréhaut.

HINTS TO AMATEURS ON GROWING AND FORCING SEA-KALE.

Of the few sorts of vegetables suitable for forcing, I am not aware of any that can be forced with such ease and economy as Sea-kale. Its delicious flavour and productiveness, even at the earliest season, have made its culture a source of profit to the market gardener; and because it can be brought to table with much certainty and little trouble when other vegetables are scarce, I am induced to communicate to amateurs and others who have small gardens, a plan I adopted some years ago to supply the large demands made upon me for this vegetable.

Having a small garden, I found it took too much space, time, and trouble, to treat Sea-kale in the usual way—namely, growing it thinly in beds, and forcing it there. I therefore resolved to grow my plants in a smaller space, and to force them elsewhere. Accordingly I selected a sunny open spot, trenched the soil 2 feet deep in November, added a little well-decomposed manure and plenty of road grit, and strewed enough common salt over the surface to well whiten the soil. All was well mixed together, and allowed to lie undisturbed until the following March. As early in that month as the ground is in a favourable condition for working, the seed should be sown 8 inches apart, in drills 3 inches deep, and if the soil is dry I prefer treading the seed in the drills previous to raking over the bed. The appearance of the plants above ground must be watched for, and their tender fleshy seed leaves guarded against the attacks of black fly, and the small black snail, by timely applications of finely-sifted soot and lime. When the plants are large enough, thinning must commence. It will be best done at intervals until the plants stand about 6 inches apart in the row; of course, care will be taken to leave all the best plants at the last thinning during the summer. The soil must be frequently stirred and cleaned, and a good supply of manure water occasionally will be an advantage.

By the middle of September fair-sized crowns will be formed, and soon after that the foliage will begin to change colour; some of this may be pulled off, and an inch or two of the soil removed from the bed in order to expose the crowns to the sun and ripen them. After about a fortnight in this state a layer of finely-sifted coal ashes over the bed will protect the crowns from slugs and mice. The latter will often attack the crowns more from mischief than hunger, and leave the pieces at the side, but they dislike burrowing in coal ashes. In taking up the roots for forcing, begin at one end of the bed, and trench out the roots carefully, as they are very brittle. Any other mode of proceeding will most likely result in injury to them.

At whatever time the first dish of Sea-kale may be wanted, preparation for forcing should be made a month beforehand. This I did in the following manner:—A sufficient quantity of heating material, such as stable dung and leaves, was collected into a heap and fermented for a week or ten days, turning it over once during that time. While this process is going on, prepare some pots, tubs, boxes, or any vessels 15 inches deep; they must be in pairs, for one has to be inverted over the other. Drainage must be secured, and the roots may be planted in any free common soil. For a pot 1 foot in diameter ten roots will not be too many.

A sufficient quantity for the first crop having been potted, and the heating material being in readiness, select a spot of ground in some out-of-the-way corner that will admit of a hole being dug 4 feet square, and 3 feet deep. Six inches of drainage should be provided, consisting of brick rubbish, wood, or, indeed, anything that is to be had. Into this hole pitch the manure, mix it carefully, and press it down firmly; then build it up 18 inches higher than the surface of the soil. As soon as the heating commences, plunge the vessels containing the plants up to the rim in the manure, and press it firmly round them with the hand. Cover these over with the corresponding part of the vessel, and let them remain. Now, in order to keep the heat in the manure, and make it rise, the whole may be covered with rough dryish litter a foot or more thick. Trial sticks must be inserted, and if the dung become too hot, which is not very likely, take off a portion of the litter. Should it become too cool, an 18-inch layer of heating material may be placed over the whole bed, including the Kale. A moderate temperature of from 50° to 60° is very suitable for Sea-kale. I ought to have said, that after the roots are potted a good watering should be given, and the water should be allowed to drain off before putting the pots in the bed. Examine them at times, and give more if wanted. If the weather is mild, a dish of Kale may be cut in three weeks, and each pot of twelve crowns ought to produce two dishes of six heads each, and if cut carefully so as to leave a part of the crown, more shoots will push forth, and another dish be secured, but the weak shoots should be pulled off. For a small supply two pots plunged at a time are sufficient, a succession being started in a week or ten days afterwards. Each bed of the above size will force four dozen roots.

I am aware that Sea-kale is forced for table in several ways, and, where conveniences are at hand, with less trouble; but as I write this paper for the amateur, and was for some years obliged to adopt any method of treatment by which I could increase the supply of this vegetable, I do not hesitate to recommend the plan to others similarly situated, and hope they will try it.—Thomas Record.

GESNERA EXONIENSIS.

Amongst the latest introductions of new plants, the beautiful Gesnera exoniensis is unsurpassed. From the easiness of its culture, the length of time it remains in flower, and its valuable qualities for the decoration of the dinner-table, it certainly deserves a place in every collection of stove plants, and cannot fail to become a general favourite. This year, early in March, I inserted two leaves in 3-inch pots containing a mixture of peat and silver sand; I plunged the pots in bottom heat, and each leaf soon formed three tubers. I then placed the young

plants near the glass in a stove, repotting them when it was necessary, and using a compost of sandy loam, peat, and a liberal quantity of silver sand, with the addition of some well-decomposed cow dung. The plants are now in 11-inch pots, show a multitude of flowers, and are 2½ feet in diameter, and one leaf measures nearly 9 inches across. In addition to the plant's beautiful flowers, its foliage is the admiration of all who see it.—William Jordan, *Cannizero Gardens.*

CLASSIFYING GRAPES—THOMSON'S WHITE LADY DOWNE'S.

Grape-cultivators have long felt the want of a really good late white Grape—one that could worthily take its place as a fitting companion to our present magnificent race of black varieties. We have, of course, had the Muscat of Alexandria itself, a white, without a black companion until quite lately; but in almost every other instance the black varieties have largely predominated over the white, and proved not only superior in quality, but in appearance also. To produce a really handsome dessert it is always necessary, to give proper effect, to employ two dishes of Grapes, one white, the other black. The most useful of our black Grapes is, no doubt, the Black Hamburgh, and of the white, Muscat of Alexandria. The first, however, although it may be kept tolerably late, is not particularly handsome in the early spring months, or a profitable variety for that season. We have had, therefore, to call in the aid of the Black Alicante (Black Tokay) and Lady Downe's. The Muscat of Alexandria, again, requiring a different treatment, and being more expensive of cultivation, is frequently not available, even if it were wanted; so that the burden of the entire late supply of Grapes rests with the black sorts, which have been without a suitable white companion until the advent of the subject of my notice—Thomson's White Lady Downe's.

The following classification of Grapes, black and white, suitable companions the one for the other, may prove of some interest. It includes only the leading varieties:—

Class 1.—	Black Hamburgh and its varieties	Black.
	Golden Hamburgh, Golden Champion, Buckland Sweetwater.....	White.
— 2.—	Madresfield Court, Mrs. Pince	Black.
	Muscat of Alexandria.....	White.
— 3.—	Alicante or Black Tokay	Black.
	White Tokay	White.
— 4.—	Gros Guillaume (Barbarossa)	Black.
	Trebbiano, Raisin de Calabre	White.
— 5.—	Lady Downe's	Black.
	Thomson's White Lady Downe's	White.

Grapes should thus, I think, be grown in classes—*i. e.*, a black and white variety of each class. It will be seen at a glance how much of similarity, both in appearance, quality, season, and requirements of cultivation, is borne by each variety in its class to the other. In the first, the black has somewhat the advantage, if we except the superior flavour of the Golden Champion. In the second the white is, undoubtedly, superior to the black. In the third the appearance is in favour of the black, the flavour, of the white. In the fourth it is so likewise; and in the fifth the black, which is well known, is now surpassed both in flavour and in its keeping properties by the white variety.

It is a fact which has often been noted that white Grapes, Grapes with light skins, keep longer plump and fresh in spring than those with black skins. White surfaces, we know, do not so readily absorb heat as black ones, and it appears to be so with Grapes. In March and April the white sorts do not absorb so much heat, which causes decay, as the black; consequently the former keep better, and in this way Lady Downe's, which is the latest black, is superseded in its keeping properties by its white offspring.

I consider Lady Downe's the best late black Grape yet in existence, and its companion is the White. Having now had for two seasons the pleasure of tasting the qualities of this new Grape as grown at Dalkeith, comparatively with the Lady Downe's growing alongside, I consider it in flavour superior to the old variety. It appears, also, to be entirely free from that peculiar tendency to scald, so annoying with the black variety. With the exception of the colour, the fruit when well grown is quite the same in all its appearances as the black, and the habit of growth, foliage, &c., of the plant are altogether the same.

The White Lady Downe's Grape is a seedling raised by Mr. Thomson, of Dalkeith, from seed taken from a bunch of black Lady Downe's, over which was shaken the pollen of Bowood Muscat. The cross, however, if there was any, seems to have been very slight. The progeny seems to partake more of the character of an ordinary sport from the old variety. Several other seedlings from this bunch were raised at the same time. One was named Golden Lady Downe's, and it had fine large berries and a fine bunch, but it proved of inferior quality, and its growth was discontinued. That name—Golden Lady Downe's, would have been the most appropriate for the variety under notice, but having been once awarded could not be again adopted. Some attempts are made to confound this variety with the former and inferior sort, from which it is totally distinct. I have also seen it advertised as Foster's White Seedling, or White Lady Downe's, the former being an early Grape, and possessed of no relation thereto whatever, further than its having been raised by Mr. Foster from seed out of the same berry as the black Lady Downe's.

The White Lady Downe's is a welcome addition to our stock of Grapes, and one which, when once its merits are known, will be extensively cultivated.—Archambaud.

AUTUMN RAMBLES.—No. 2.

One main object that I propose to myself in jotting down these few notes of an autumnal tour is, that if any brother horticulturist be led into the same byways as myself, he may know where to see what will suit his taste, and perhaps give him a hint in some of the many departments of our loved art. Nothing can be more provoking than in going to a place, to trudge off, it may be on a hot summer's day, to some place with a grand name, which you have picked out from a directory, and then to find that the owner has no care or love for flowers, and that it is only because it belongs to a lord or baronet that it has been inserted in the list; almost equally annoying is it to find that you have omitted some place where the owner is an enthusiastic lover of flowers. It is not every one who has an acquaintance in a strange place, or who knows exactly what you want; so it might have been at Norwich, but my son knew my wishes, and so prepared for me the treat I enjoyed so much. I do not pretend to give full descriptions of the gardens visited—in the first place, because they always seem to me to convey at best a poor notion of them, and secondly, because very few people care to read them. Thus my notes of Mr. Colman's were very brief, but I hope sufficient to induce others to visit his place; equally so will be those of the other two places I saw on the same day. Crossing the river close to Mr. Colman's the road leads up to Thorpe hamlet, one of the suburbs of Norwich, where a large number of those who are engaged in the city have their residence, and after a short walk we come to

THE RESIDENCE OF ISAAC B. COAKS, ESQ.

The house is situated on an eminence and overlooks the valley, while the towers of the cathedral and city churches, the citadel, &c., are to be seen in the distance. The house and grounds are both new, and a few years ago the place was a rough uncultivated piece of ground, but its present aspect betokens both a considerable amount of skill and perseverance, and also good taste. In the front of the house there are some good plants of Conifers which, after they have been there for a few years, will have a fine appearance. Amongst them I noticed some good plants of Thuja aurea and Wellingtonias.

The house stands on a terrace, and on one side is a fine conservatory of an ornamental character, in which were, amongst other usual occupants of such situations, some good plants of the new Golden Coleuses, which are very well suited for conservatory decoration, the finest being, perhaps, Baroness Rothschild, Her Majesty, and Princess Royal. On the other side of the house is a small sunken parterre, which is the extent of the bedding-out. I have never seen Mrs. Pollock Pelargonium in such robust health as in these beds; if it always did look like that no one would ask for a finer one in its class, or rather style, for there are two distinct styles—the pointed serrated leaf, such as Mrs. Pollock, Sophia Dumaresque, and, indeed, all Mr. Grieves's strain, and the round-leaved one, such as Sir Robert Napier, Mrs. Dunnett, Moonstone, &c.

Passing round by this parterre, you come on a range of low houses most admirably suited for the cultivation and growth of plants, and filled with a capital selection of stove and greenhouse plants, Orchids, and Ferns. Mr. Coaks is a very successful exhibitor; and although it is the fashion to find fault

with such places, and people say, "Oh, everything is sacrificed to the exhibition!" yet somehow one is sure to find in these places plants worth looking at, either for their novelty or good cultivation. I saw here some young plants of Geonomas, Livistonias, and other Palms. Ferns are also largely grown; amongst them I saw plants of what are as yet the finest in their respective classes, for surely nothing can exceed Todea superba amongst the Filmy Ferns, or Adiantum farleyense amongst the Maiden-hairs. Orchids, too, were also grown, and although not in large quantities, yet appeared in healthy condition—in fact, all the plants betokened careful and scientific cultivation, while plants of interest of recent introduction were evidently being added as their characters became established.

THICKTHORN HOUSE, THE SEAT OF F. WATSON, ESQ.

This is situated about four miles from Norwich, in a good-sized park. The house itself is a plain substantial building, containing some fine and well-proportioned rooms; and if anyone were to visit the place with the idea of seeing one of our new-fashioned gardens he would be greatly disappointed, for it is one of those old-fashioned ones with borders filled with many of the herbaceous plants banished from modern gardens, but which at all times furnished abundance of flowers of varied hues and forms, and the returning taste for which is to me one of the hopeful signs of horticulture. And yet I found here one of the prettiest pieces of bedding I have seen for some time. I do not recollect exactly the flowers with which the beds were filled; there was nothing uncommon in them, I am sure, but the situation and surroundings were pleasing. The site had been either a gravel pit or quarry; there was a small piece of water, a beautifully-kept sward, some nice foliage surrounding a croquet ground a little further off, and, altogether, it was very delightful. There was in the garden a goodly range of glass, but there were no plants in it, but a fine crop of Grapes, mainly consisting of Black Hamburghs and Muscat of Alexandria—just such houses as one would like to have oneself. There was no affectation of doing anything grand, no disbudding to grow huge bunches for exhibition, but a good honest crop of fairly-sized bunches, and this effected without any great, or, rather, extravagant cost, for this, I rather think, is a consideration not taken into account in the wonderful results of modern Grape-growing. What we want for general adoption is a system that will suit the pockets of those who are neither millionaires nor milords, and such a system seemed to be in use here.

I have thus attempted to give a very faint notion of my horticultural rambles round Norwich. I may not have visited places which were equally worth seeing, but I enjoyed my ramble very much. Each of the three places I went to represented different styles, and I may, perhaps, add different tastes; but they were all to my mind well worth seeing, especially as indicating how widespread is the love of horticulture amongst us, and how much of kindly feeling there is in the brotherhood of gardening.—D., *Deal*.

OCTOBER.

THE October of this year has been peculiarly trying, particularly among late orchard fruit where there were a few left, for we were visited with some very heavy gales, chiefly from the north-west to north-east, which blew off Apples and Pears, beating and bruising others, and spoiling them for keeping purposes. What with frost and piercing wind, the trees in one day and night had the appearance of being scorched. I never remember having seen the like before; we had trees brought down by the force of the wind, and large limbs torn off others. Winter Greens, Cauliflowers, and Broccoli have suffered much, being twisted about in all directions, and many of the large leaves altogether broken by the force of the wind. Some of the plants were almost torn up, many of them lying level on the ground. On the morning of the 19th the thermometer at 6 A.M. indicated 6° below freezing point, but the air being dry at the time I am inclined to think we suffered more from wind than frost, as Pelargoniums, Verbenas, and other plants left out of doors were not blackened by frost.

At the beginning of the month we were much annoyed by caterpillars of different kinds, but by constant picking most of the Cabbage tribe are now pretty clear. We had here a bed of Black Prince Strawberry plants in bloom, but the winds have destroyed them. Several Apple trees had some fine clusters of blossoms open before the storm, but they were swept away. A second crop of Marie Louise Pears on orchard trees promised at one time to arrive at a moderate degree of perfection, but it is all over with them now. Celery has suffered much; most of the leaves have been blown away altogether. The Potato disease has shown itself among late kinds; Haigh's or Lapstone Kidney appears to be most affected. Some that were supposed to be free from disease when lifted have become bad, though they were selected and stored away dry, and with care. It has been a very severe month, and will long be remembered by many.

PLANTS FLOWERING IN OCTOBER.

4th. Magnolia grandiflora
Abronia umbellata
Francoa sonchifolia
Calendula Pongei pleua
Callirhoe verticillata
Carduus benedictus
Aster chinensis
Apples
Lupinus pubescens
mutabilis
Menziesii
Acanthus mollis
Acrochinium roseum
Ipomœa hederacea
Quamoclit
Leasa aurantiaca
Rose, Monthly China
Fabvier
Malcomia maritima
Physalis Alkekengi
Getaurium nobosum
Rudbeckia fulgida
Neumannii
Aster tenellus
Cacalia coccinea
aurea
Alonsoa incisifolia
Ammobium alatum
Campanula alliariæfolia
grandis
Lorei alba
persicifolia
Anemone japonica
Cineraria maritima
Convolvulus mauritanicus
Heliotropium peruvianum
Eschscholtzia alba
Dianthus Caryophyllus
Clematis Vitalba
Viticella
Delphinium formosum
Arctotis breviscapa
Argemone grandiflora
Celosia pyramidalis
Commelina cœlestis
Armeria formosa
Artemisia annua
maritima
vulgaris
Centaurea argentea
gymnocarpa
Lychnis Dis-Jovis
Malope grandiflora
8th. Myosotis palustris
Pyrethrum Golden Feather
Nemophila insignis
Nigella hispanica
Pectis angustifolia
Pentstemon coccineum
venustum
Aloysia citriodora
Colchicum autumnale plenum
Erica ramentacea
stricta
Hordeum jubatum
Cyclamen europæum
hederæfolium
Xeranthemum purpureum
Centaurea moschata
Malva zebrina
moschata alba
Nicotiana virginica
Orobus coccineus
Mimulus tigrinus
Nolana paradoxa
prostrata
Perilla nankinensis
Petunia grandiflora
Sanvitalia procumbens
Portulaca splendens
Rudbeckia amplexicaulis
Maurandya Barclayana
Mesembryanthemum glabrum
crystallinum
Obeliscaria pulcherrima
Nierembergia gracilis
Œnothera macrocarpa
Lamarckiana
taraxacifolia
Salpiglossis coccinea
Phlox Drummondi
Sedum cæruleum
Tolpis barbata
12th. Echinops sphærocephalus
Stipa pennata
Crepis rubra
Silene Schafta
rubella
Viola cornuta
Propæolum canariense
Chrysanthemums, various
Schizostylis coccinea
12th. Lavatera trimestris
Mirabilis Jalapa
Nasturtium Tom Thumb
Matthiola annua
Statice formosa
Limonium
latifolia
Salvia Horminum purpurea
Convolvulus major
Tagetes patula
erecta plena
Leycesteria formosa
Coronilla Emerus
Achillea compacta
Asperula odorata
Aster ericoides
lævis
Amellus
Campanula carpatica alba
pumila
Centaurea candidissima
Aubrietia deltoidea
Gazania splendens
Geranium sanguineum
16th. Gnaphalium lanatum
Helianthus annuus
multiflorus
Lamium aureum
Oxalis Bowieana
floribunda
Lilium lancifolium album
Hypericum calycinum
Koniga maritima variegata
Linum alpinum
Santolina alpina
incana
Tritoma Uvaria
Phlox decussata
Stenactis speciosa
Plumbago Larpentæ
Viburnum Tinus
Cydonia japonica
Veronica speciosa
salicifolia
Andersonii
Aster cordifolius
Alyssum maritimum
saxatile
Calceolaria pinnata
Ruby Bicolor
Aurea floribunda
Ionopsidium acaule
Jasminum fruticans
Lavandula Spica
Linum flavum
perenne
grandiflorum
20th. Anagallis grandiflora
Breweri
Arbutus Unedo
Helichrysum album
Cuphea platycentra
strigillosa
Gaillardia picta
Digitalis aurea
Antirrhinum majus
Lathyrus superbus
latifolius
Dracocephalum sibiricum
26th. Gynerium argenteum
Amaranthus tricolor
Ageratum mexicanum
odoratum
cæruleum
Calandrinia umbellata
Anchusa sempervirens
italica
Brachycome iberidifolia
Calliopsis Atkinsoni
Drummondi
Datura Stramonium
Coronilla glauca
Lobelia fulgens
St. Clair
Rose Gloire de Dijon
Crimson China
Verbena venosa
pulchella
Zauschneria californica
Salvia bicolor
speciosa
fulgens
Dracocephalum canariense
Centaurea Cyanus
Bidens atropurpurea
Zinnia elegans plena
Delphinium Consolida
Ajacis
Reseda odorata
Mimulus moschatus
Briza maxima
Amaranthus speciosus

—M. H., *Acklam Hall, Middlesbrough-on-Tees*.

BUDDING VINES.

THIS practice I can strongly recommend as the best plan of working Vines both as to neatness and quickness of results.

This method has been adopted by Mr. J. Sheppard, of Wolverstone Park, for some ten or twelve years with good results; he has two large vineries there, and I believe all the Vines are

worked in this way. I witnessed the budding of one Vine about three or four years old: the bud was taken from a piece of half-ripe wood and cut in the same way as a Rose bud, only leaving a small portion of wood on the bud; then the bark of the Vine close to where the latter entered the house was carefully raised, the bud put in, and bound up with a piece of matting. This was done about the time the Grapes were colouring on the Vine in which the bud was inserted, and the bud remained dormant till the Vine was started in the spring, when it grew and made a rod the same year as thick as one's thumb, and from 12 to 14 feet long. This mode of working Vines can be practised without any loss, as you can have a crop of Grapes on the old Vine at the same time, and when the young rod arrives at a bearing state the old one can be cut away and the young one be left.

Whether this is an old or new practice, Wolverstone is the only place where I have ever seen it pursued, and I have spoken to many gardeners on the subject, and I have never met one as yet who had heard of it or seen it. No doubt there are plenty who have had more experience in budding Vines than I have had, and I can only answer for budding two Vines, and both successfully. I do not know if this is the mode adopted by Mr. Stevens, but should like to see a description of his system in your paper.—J. L., *Higham Court.*

ROYAL HORTICULTURAL SOCIETY'S JANUARY SHOW OF FORCED SHRUBS.

I much need to know why do not the Committee of the Royal Horticultural Society issue their schedules at an earlier date? Some time ago an advertisement appeared in "our Journal" stating there would be a show held on the 19th of January for "forced Shrubs." I think it is, therefore, quite time that we should have the details of this exhibition, as any one desiring to exhibit on that occasion ought, I should think, to be now preparing his plants for blooming, and how is he to know what to prepare? Supposing, for instance, that I wished to exhibit, and that I had prepared three Rhododendrons, and had bloomed them well, when the schedule arrives I find that I cannot enter my plants because six are required. This would be very aggravating, and I think the case I have stated is not at all an unlikely one to happen. Again, we do not know whether amateurs will be invited to compete or not. In fact, we know that a show is to be held, and that is about all, and we are within six weeks of the time. Not only would exhibitors benefit by an earlier announcement of the Society's intentions, but the Society itself would receive a large benefit, as it would have a better show. The Committee may say, perhaps, "We cannot yet make arrangements for next summer, and our arrangements are all included in one schedule." Then I say, Let us have two: a spring schedule and a summer schedule; this would overcome the difficulty.—A Subscriber.

BOILERS AND BOILING.

Gardeners know that fire applied at the top of a boiler will not heat the water; they unjustly blame the fire for not doing so. Mr. Peach declares it does heat the boiler: perhaps it does, but it certainly does *not* heat the water to any extent. Mr. Peach compares a boiler with an oven, this proves he did not reflect. Water is boiled by convection—that is, as soon as the fire is applied underneath a boiler containing water, the hot particles of water ascend and the cold particles descend until the whole is heated. Water being a bad conductor of heat, it is practically impossible to boil it by putting a fire above it. Science and practice have proved the relative value of heating surfaces to be—

Horizontal surfaces above the flame	1.00
Vertical	0.50
Horizontal surfaces beneath flame	0.00

—(From Molesworth's "Engineers' Pocket-Book".)

I should advise all persons interested in this subject to read Tomlinson's book on "Warming and Ventilation."

As to the setting of any boiler, the furnace should be high, as this is favourable to combustion. If the boiler is close down on the fire it chills the gases evolved during the combustion of the fuel, and they pass off unconsumed. The fire-bars should extend beyond the front of the boiler; in other words the front end of the boiler should be at least 1 foot away from the furnace door.

I do not exactly comprehend what Mr. Peach means by "the feed-pipe, too, should be one of large diameter, as the pressure on the boiler is inversely proportionate to the square of the radius or diameter of the pipe." This is a mistake, the pressure depends on the height of the pipe irrespective of its diameter. For instance: a pipe 34½ feet high filled with water would cause a pressure of 15 lbs. on the inch to be exerted on the boiler to which it was attached. Were the pipe 1 inch, or were it 20, in diameter, the pressure would be the same on the inch. For rough purposes it may be said the pressure per inch on the boiler is equal in pounds to half the height of the feed-pipe in feet, when such pipe is filled with water. By increasing the pressure, the boiling point or temperature of the water at boiling is increased, and, of course, the consumption of fuel.—John Woolfield, *Soho, Birmingham.*

AMERICAN BLACKBERRIES.

Your correspondent "Rubus," in the Journal for September 16th, must have been unfortunate with his Lawton and Dorchester Blackberries, if they were not so fine as the wild English species. Here the Lawton is at least four times as large as the average English fruit, makes a very handsome dish, and when thoroughly ripe the flavour is excellent, quite different from the flat insipid flavour, or rather want of flavour in the English sorts. I had not formed a favourable opinion of Blackberries in general previous to tasting them here, but can now say that although mine is not a juvenile taste, they are a capital fruit both raw and cooked, and I have not heard of its being necessary to mix Crabs or wild Apples to improve the flavour in tarts and puddings, which I have seen done in England.

I recollect a short time ago reading in a gardening periodical that the fruit of the Prickly Pear was sold for dessert in the American market. According to this showing, the American people are in the same state of civilisation as the ancient Britons, which we should scarcely expect to be the case when excellent Peaches can be bought at 2*s.* 6*d.* a-bushel, Apples at less money, Strawberries at 2*d.* the quart, Pine Apples at all the fruit stalls at 1 cent. or less than a halfpenny per slice, and Bananas at the same scale. I am anxious to know the percentage of young folk in England who taste all the above fruit, to say nothing of eating their fill of them, and not once but continually.—James Taylin, *South Amboy, New Jersey, U.S.A.*

TOMATOES IN ILLINOIS.

The sons of a labouring man in this parish, who are settled in Illinois, U.S., in writing to their parents sent them some Tomato seed, and in offering a few of them to me they brought the letter for me to read. It has occurred to me that you might like to insert in your Journal what these young settlers think of the Tomato, and their way of cultivating it in their adopted country. They say—"Tomatoes are very nice to eat; we like them as well as Peaches; they are good to skin them, and sliced up and sprinkled with sugar to eat at table like Peaches. They are good stewed-up with pepper and salted. We like to pick them off the vines and eat them out of hand, but most people do not like them except for table use. You sprout them in a box like Cabbage, and set them out 3 feet apart. The vines grow like Potato-tops. The fruit on the vines is nearly as large as your fist, and red or yellow when ripe."—W. B. Capern, *The Vicarage, Draycot, Weston super-Mare.*

PRINCE OF WALES POTATO.

I have grown this Potato for several years, and it is a great favourite of mine. When I first became acquainted with it my ground was in a very unfit state for gardening, but being persuaded by a friend of mine I purchased 7 lbs. of seed. I prepared a piece of ground, and planted the seed on May 27th, 1865, and took up the produce about the middle of September. To my great surprise, when I weighed it I had somewhat more than 2 cwt.; I never saw such a yield before, and some of the tubers were very large. I have continued to grow this variety every year since, and although it has not yielded as it did the first season, still it is the most productive of any second early Potato I know.

Prince of Wales Potato has one disadvantage—it is rather subject to disease, but if the tubers are lifted as soon as the haulm begins to decay there will not be much to complain of. The flavour is not quite so good as that of Myatt's Prolific Early Ashleaf Kidney, not being quite so dry. I planted this

year a large breadth of the Prince of Wales by the side of a quarter of an acre of Myatt's, and the produce of the former was more than as much again that of the latter, although the ground was treated alike in both cases.—E. Feazey, *Balsall, Coventry.*

GRAPES WITHOUT FIRE HEAT.

In April, 1865, against a wall facing south by east, I erected a lean-to Vine house after Paxton's principle, upon 4-feet brick piers. The house measures inside 21 feet by 11, and is covered with 11-feet glass sashes. The whole border (10 feet wide outside and 11 feet within) was first covered with 1 foot thick of brickbats, broken stones, and hard mortar, and afterwards up to the piers, and sloping inwards and outwards, with common garden soil. At the end of April and beginning of May I planted eight Vines inside, nearly on the surface, and covered the roots of each with a small quantity of powdery, dry manure. The kinds were White Frontignan, two Black Hamburghs, Grizzly [Red] Frontignan, Lady Downe's, Buckland Sweetwater, Foster's White Seedling, and Trentham Black.

In 1866 I only had a bunch from each; in 1867 about ten bunches from each; and in 1868 I had an average of twenty from each, the greatest weight being 2¾ lbs. This year I have picked 203 bunches, and only had two red Grapes on the Black Hamburgh and two on Lady Downe's. I encourage as much leaf as possible, thin early, and my ventilators at each end at the top have not been closed since March. I use the syringe freely, except when the Vines are in bloom, and give abundance of air whenever practicable.

The Grizzly Frontignan this year was excellent, with berries larger than usual, and very little shanked. The White Frontignan and Buckland Sweetwater ripen first, beginning about August 20th. Many bunches of the Buckland Sweetwater were upwards of 1 foot long, but, being a light Grape, none weighed more than 1 lb. I gathered the Lady Downe's yesterday (November 30th), to keep for Christmas, also two bunches of Foster's White Seedling, which hangs well.

Being within two miles of the sea, I cover the outside border 6 inches deep with seaweed early in October, rake it off in April, and then fork thinly in a coat of rotten manure. The inside border also has a slight manure-dressing.—W. K., *Angmering, Arundel.*

FLUE-HEATING.

I am glad that the very able writer of "Doings of the Last Week," in referring to boilers and hot-water heating, did not omit the still useful mode of doing so by the "old flue," which as a heating agent has been often unduly disparaged, considering the long and good service it has done in bygone years, and still continues to perform in many places; indeed it is a problem now amongst many well versed in the matter whether heating by this means has not been too suddenly abandoned. Certainly, at the present day, the hot-water apparatus manufacturer's calling has many professors, while a really good flue-constructor is not easily found, so that when an economical gardener or amateur wishes to convey the smoke from his furnace in a horizontal direction he has much of the duty of giving directions, if not of performing the actual work, thrown on his own shoulders. And however cheaply glass structures may be erected, it is very unpleasant to one who has just had a house put up to be told that he must expend nearly as much as it has cost him to have it heated. This is no unusual case, as the hot-water apparatus, however economically erected, constitutes an expensive item in the heating of small or single houses. Where there are a number of houses, the cost is proportionably much cheaper. Still, many of the most ardent votaries of gardening can only afford one house; and to keep the frost out is a matter of importance, as, unless this be done, it is next to useless. I was, therefore, much pleased with "R. F.'s" description of a cheap flue, and I do not think he will quarrel with me for describing a somewhat similar mode of heating adopted here many years ago, which has answered exceedingly well, and which, I think, is suited to all similar places where only a moderate warmth is wanted. Where coals are cheap I am not sure whether it will not compete in utility and economy with the most skilfully-constructed hot-water apparatus, if applied to forcing houses and the like.

About twelve years ago two plant houses were put up here for ordinary greenhouse plants, and it being thought at the time that some future alterations might occasion their removal, an expensive hot-water heating apparatus was not thought desirable if it could be avoided; recourse was therefore had to a flue, but instead of the square brick flue described by "R. F.," socket pipes were put in on the straight lines, and ordinary brickwork at the turnings. The pipes were 12 inches in diameter inside, and 30 inches in length. A slight foundation was put in at the joints only, the pipes in other respects being clear of the ground. This pipe flue has been in use ever since, and seems likely to last as long as can fairly be wished; it has been once or twice cleaned out by taking off the covers of the brickwork corners, which are more convenient than bent pipes would have been there. The pipes being only about 1½ inch thick, heat quickly, and answer every purpose required. I ought also to state that they are made of cement, part of them being of Roman and part of Portland cement. The latter kind, I am told by a skilful maker at Maidstone, will endure almost as much heat as firebrick; certainly they answer their purpose very well in my case, and I would strongly recommend them to all who require a house heated cheaply. The price of the Roman cement pipes at the time they were purchased I believe was 1*s.* 1*d.* per foot run, and that of the Portland cement pipes 1*s.* 6*d.* The setting is a very simple affair, the joints fitting into each other, and requiring but a small quantity of cement to make them smoke-tight, and the appearance is good. As cylindrical pipes for draining purposes have superseded the horseshoe-shaped tiles of earlier make, as well as the brick and stone drain, so I expect the pipe flue will in like manner predominate over the square one where flue-heating is adopted.—J. Robson.

WATER RENDERED CHALYBEATE.

This is mentioned in the number of October 21, page 321, and I write to state that some years ago I substituted an iron for a wood (oak) pump. The iron, however, had not been down long before it affected the water, and I replaced the pump again with an oak one. Wood pumps will only last a certain time, and the "trees" often prove, or become, defective from other causes than actual decay; they are also cumbersome to lift and repair. I have now for some years, whenever a new pump has been required at a farm house, put down a lead one, and I have used several. There has never been any complaint about them; they cost less than wood, and are practically imperishable. I am aware that some people consider lead deleterious to the water, and there is no doubt some water does appreciably act upon lead, but this is rather the exception than the rule; and it must be borne in mind that water from a lead cistern, where there is a large surface of lead exposed to a small and stagnant body of water, is not the same thing as the surface which a 3-inch pipe would expose to water constantly renewing. My present residence is now, and has been for many years, supplied with water conveyed by a lead pipe, and being from a reservoir considerably above the house, the pipe is always full, and the water stationary when the taps are not used. The water is remarkably pure and good. Old lead, too, when done with, is of considerable relative value to the original cost.—V.

ENTOMOLOGICAL SOCIETY'S MEETING.

The second meeting of this Society was held on November 15th, the President, Mr. H. W. Bates, being in the chair. Amongst the donations to the library announced by the Secretary, was the fifth volume of Gemminger and Harold's Catalogue of Coleoptera, and the third volume of the Royal Society's great Bibliographical Index.

Mr. F. Smith exhibited on the part of Mr. Edwin Brown, of Burton-upon-Trent, a very fine species of Locust, recently captured in the neighbourhood of that town, and which was found to be identical with an unnamed species in the British Museum, from Northern Bengal. He also exhibited a series of specimens illustrating the economy of Rhipiphorus paradoxus, a curious Beetle which resides as a parasite in the nests of the common Wasp. In a paper in the last number of the "Annals of Natural History," Mr. A. Murray had endeavoured to prove that this Beetle only took up its abode in the Wasp's nest as a retreat, and not with the view of feeding upon the Wasp-grubs or pupæ; but the late Mr. Stone had worked out the entire history of the parasite, and had found its larva with the head completely immersed in the body of the Wasp larva, which was sucked dry within the space of forty eight hours, the parasite growing as rapidly. Specimens in this position were exhibited by Mr. Smith. The late Rev. F. W. Hope had also made an observation, which showed the parasitic connection of the insect with the Wasp, to the effect that amongst the Rhipiphori certain specimens were found of a gigantic size, and these had been reared in the enlarged cells, and had fed on the much larger grubs of the queen Wasps. Professor Westwood also cited the observations of

the late Rev. Lansdown Guilding upon Horia maculata, the larva of which (as shown in one of Mr. Guilding's drawings, which had not been published with his memoir), feeds upon the larva of Xylocopa.

Mr. Pascoe exhibited a number of new Heteromerous Beetles, collected in Australia by Mr. Masters, including a species of Helæus, covered during lifetime with a white secretion, which had been considered by some botanists to be a fungus, but Mr. Wallace thought it extremely doubtful that such growth should have taken place whilst the insect was alive, thinking it more probable that it was an animal secretion, like the pollinosity on certain species of weevils.

Mr. Briggs exhibited a fine specimen of the very rare Moth, Deiopeia pulchella, taken on the 1st of October last near Folkestone. During flight it completely resembled Geometra dilatata. Mr. Davis exhibited a series of beautifully-preserved Lepidopterous caterpillars, together with a case containing a complete series of illustrations of the economy of the Goat Moth.

Mr. Albert Müller made some observations on the peculiar scent emitted by Cynips lignicola and another Oak-gall Fly when handled, which he considered served as a preservation against the attacks of birds. Mr. Salvin read a memoir on Clothilda, a genus of beautiful American Butterflies, of which he enumerated and exhibited six species. The President read a memoir containing descriptions of a number of new species of Longicorn and Lamellicorn Beetles, captured at Chontales, Nicaragua, by Messrs. Belt & Janson. A paper was also read containing descriptions of new exotic species of Hispidæ, by Mr. Baly.

Some observations on the vast swarms of Syrphideous Flies, observed during the past autumn at Ramsgate, Bournemouth, Walton-on-the-Naze, and other parts of the southern and eastern coasts of England, were made by Messrs. Horne and Dunning. After considerable discussion it appeared to be generally considered that these aphidivorous flies, as well as the great swarms of Lady-birds noticed about the same time, had been reared in this country, and had not flown across the sea from abroad, the vast numbers of Aphides previously observed being sufficient to account for the proportional increase in the numbers of their enemies. Mr. Janson especially mentioned that an Apple tree in his garden in the suburbs of London, which had been completely covered with the American blight (Aphis lanigera), was completely cleansed of these insects in three or four days by flights of Lady-birds, myriads of which had visited the tree in the early autumn.

NOTES AND GLEANINGS.

Mr. William Melville, so favourably known for his successful raising of new varieties of vegetables and Grapes, is leaving Dalmeny Park Gardens, after presiding there thirty years. He is only sixty, and in good health, but the Earl of Roseberry has settled on him a life annuity of £60, and he intends to devote himself to his favourite pursuits in the island of Jersey.

—— At the meeting of the Royal Horticultural Society, to be held on Tuesday, December 21st, prizes of £3 and £2 are offered by the Rev. G. Kemp for the best winter dessert of Apples and Pears, three dishes of each.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Continue to trench, dig, and ridge-up every piece of spare ground when frost permits. This is particularly to be observed in soils approaching a clayey nature. If frost continue let the manure necessary for the whole of the spring cropping be wheeled out, laying it in heaps either on the spot or as near as possible to it. That portion not required for immediate digging-in should be piled in small mounds and covered with soil to prevent loss.

FRUIT GARDEN.

The principal work in the fruit department is pruning. Planting ought to be completed; if not, unless the weather be very mild it will be better to defer it until spring. The directions previously given with regard to pruning bush fruit trees are still applicable. If dressing with hot lime and soot when the trees are wet were more attended to, we should not hear so much of the ravages of birds among the buds, and I would recommend the application of these substances also to standard Plum trees wherever practicable, as they not only keep the trees free from moss and lichen, but assist in the extirpation of those insects in the search for which birds commit such ravages. Dressing with fresh-slaked lime is still more imperative as regards Apple trees which are situated in damp localities, where mosses and lichens spread with great rapidity, and, if not checked, are very injurious to the well-being of the trees, besides affording a secure harbour for numerous insects during the winter. The effectual remedy, however, for all such evils is thorough drainage. Continue the pruning and training of wall fruit trees in open weather; also prune and dress pyramid and espalier Apple and Pear trees, after which apply top-dressings of compost, and fork them in slightly so as not to interfere with the roots. This operation is very necessary where a regular system of root-pruning is persevered in, because one object in root-pruning ought to be to keep the roots near the surface, and these will require to be often encouraged by the addition of fresh compost, otherwise there will always be a tendency to push their long feeders out of bounds in search of food. Do not forget former remarks on top-dressing the ground about orchard trees, which are also all the better for such attention. Gishurst compound in the form of a strong lather is also recommended for the same purpose. Make cuttings of choice Gooseberries and Currants, also Honeysuckles in the same manner, and Irish Ivy for covering naked fences. Look over fruit and other stores frequently.

FLOWER GARDEN.

Those who are fortunate enough to have the command of a gravel-pit should secure a good supply of gravel whenever the weather is suitable for the work. See, also, to having plenty of soil prepared for striking cuttings in the spring, and have draining materials for pots prepared and sorted out in sizes. If any of the more tender kinds of Roses are yet unprotected, some covering material should be applied at once. Dahlias temporarily placed roots upwards under cover to dry, should now be carefully stored for the winter. See that coarse-growing plants which may be encroaching upon their weaker neighbours are reduced so as to occupy their proper places. Gladioluses may still be planted, and most kinds of bulbs are better now in the ground than out of it. For Gladioluses choose a warm thoroughly-drained situation; work the soil well by deep digging, and add plenty of decayed manure; elevate the bed or patch a few inches above the general level, plant the bulbs 5 or 6 inches deep, and 6 inches apart, surrounding them with 1 inch of sand before covering with the soil, and protect during the winter against excessive wet and frost, by a thick layer of sawdust, old tan, dry litter, an old carpet, thatched frame, or tarpaulin. The last three coverings must be removed during favourable weather, and the other coverings entirely cleared off when the plants appear. The tops of standard Roses worked on ordinary stocks may be protected by wisps of straw bound amongst and over their branches, or by light canopies firmly fixed. Beds or masses of Hybrid Perpetual, Tea-scented, and other Roses should have some porous material strewed amongst them to protect the collar. Cocoa-nut fibre refuse, and exhausted tan from the Pine-pit clean-riddled, using the coarse particles, are very good; even a coat of half-decayed leaves will answer the purpose. Four or five inches of such material may keep them safe in the event of a severe winter. If it is desirable to protect the tops altogether, mats thrown lightly over them will suffice, taking care on the breaking-up of frost to expose the trees cautiously, and not until after they have thawed. As there will be comparatively little to do at present, any spare time will be well spent in going over the stock of plants in pits for next season's use, removing every decaying leaf, and where the surface soil has become green removing this and top-dressing with sandy loam. There is nothing so unfavourable to these plants at this season as damp; therefore, take every favourable opportunity of admitting fresh air.

GREENHOUSE AND CONSERVATORY.

If the weather should continue frosty the conservatory will require great care in its management. Atmospheric humidity cannot by any means be entirely dispensed with, yet this, if unskilfully applied, will produce drip, which is most prejudicial to the delicate texture of Camellia blooms and other gay plants. The best plan is to keep as low a temperature as can possibly be allowed—say from 40° to 45° at night, and to give a little air at the back and front all night, if the weather be favourable. The front air must be very moderate, or the atmospheric moisture, instead of passing quietly away by the back apertures, will be condensed as it rises. With a good roof-covering, in the case of small conservatories, 40° would be sufficient, and then there would be atmospheric moisture enough at all times without the special application of water. See that young stock in mixed greenhouses, such as Heliotropes, Scarlet Pelargoniums, Cyclamens, and other flowers grown especially for winter, have light situations and regular attention as regards water. Let Cape Heaths have close attention as regards watering; if, unfortunately, they stand near flues or pipes, they may become suddenly very dry. Keep up a quiet ventilation day and night if possible, let the air steal in moderately, and dispense with strong fires. Do not water Pelargoniums until they are tolerably dry, and take care to fumigate frequently and slightly. This is a good time to introduce into the conservatory forcing-pit the follow-

ing plants, provided they have received the necessary treatment during the summer—viz., Rhododendrons, Azaleas, Persian Lilacs, Sweet Briars, Moss and Provence Roses, Crimson Perpetual Roses, Ledums, Kalmias, Anne Boleyn Pinks, Wallflowers, Sweet Williams, and Dutch bulbs. Unless, however, they are in proper trim it will be labour in vain, and no mode of forcing nor form of pit can compensate for this. The great secret, if the heat wholly consists of fermenting materials, is to keep down accumulating damp and mouldiness by almost constant ventilation, increasing the linings in order to raise the necessary temperature. Those who possess properly-heated houses or pits will, however, as a matter of course, pursue a somewhat different method. In pruning and training climbers in these houses, some regard must be paid to the time when it is desirable the plants should bloom. Thus, with stove climbers not required to flower before autumn, pruning may be deferred for some time, but for earlier display it should be done at once. Passion-Flowers, Bignonias, and similar plants which make long annual shoots, should only have their branches thinned and slightly shortened, while others, as Combretums, may be spurred-in. Kennedyas will soon be showing bloom, and what training they require should be done at once, but the pruning of these should not take place until after they have bloomed. When Orange trees are grown to decorate the flower garden in summer, care should be taken to prevent their pushing in winter, and this more especially if the trees are in a dark-roofed house. When growth occurs under these conditions the leaves have always a thin flabby appearance, and soon turn brown after the plants have been set out of doors; whereas, if growth is prevented till the trees are in the open air, the foliage will bear any amount of sunshine.—W. Keane.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Cauliflowers.—Those laid by in an earth pit, coming in well, have had to be watched, and care taken to catch rats. If the rats would take a head and use it up, it would not be so bad; but one intruder will most likely go over a score of heads and render them more or less unsightly, and even if the parts nibbled by them are neatly cut out, it is not pleasant to think that you are partaking of the leavings of a rat. However, to partake of many things with a relish, it is quite as well not to be too inquisitive as to the processes through which they have passed. In a wet day we managed to fresh glaze the moveable tops of our hand-lights, though the many-cornered pieces make it a troublesome job. These would be more expensive than they are, only much small glass can thus be brought into use. We lately stated that small boxes would be better in every way. The main point now with all plants under hand-lights, is to keep them from soaking rains until the days lengthen in spring. We have tried keeping young plants in frames, in small pots, and protected at the foot of walls and planted out; but on the whole, placing small plants under hand-lights late in autumn has been the best for affording us early cuttings in May. All such plants can scarcely be kept too hardy until the sun gains strength. Full air is therefore always given in mild weather, unless it be wet, when the top is merely lifted up a little. A little frost does them no harm. If the leaves are frost-crusted a little, we have had Cauliflowers covered up in continued frosty weather for weeks. Provided there can be no growth, continued darkness will do them no injury. A night of three weeks or a month in duration will not affect them more under these conditions than one of the usual length in winter. In the good old-fashioned winters, when we used to have keen frost for a month at a time, on uncovering such Cauliflowers, we did not let them have the full sun for a day or two, and made sure they were nicely thawed before uncovering. In such keen frosty weather, accompanied often with sunny days, those who consider light to be everything, would uncover their Cauliflowers to let the sun act upon them, and thus, from being excited, they would be more likely to suffer from the keen frost at night. Under these circumstances, provided the plants were first slightly crusted, it would be better to let the covering remain, to keep out alike the heat of the sun and the intensity of the frost. Under other conditions, where a low temperature is secured, but where crust-frosting, however slightly, would be dangerous, letting in a little sun heat and light would often be useful, even for raising the temperature a little.

When we want Cauliflowers very early, we thin the plants under glasses carefully to four or five in March, encourage them by sun heat, giving less air, shutting-up early, and protecting in cold nights, so as to have the plants large and strong before being compelled to spread them out by raising the glasses on bricks, &c., at the corners.

We have scarcely had to replace a young plant in this season of grubs and slugs, and this we attribute partly to carefully forking over the ground, and looking for enemies narrowly, working into it some hot burnt earth and ashes, planting when these had time to cool, and using rough road drift for a slight surfacing. Those under hand-lights now, were planted openly in squares, and have not been long covered. Those of our readers who have no glasses may have Cauliflower early by potting small young plants singly in small pots—say 3-inch pots, keeping them under protection, giving the plants more room after the turn of the day, and planting them out in finely-pulverised soil in the middle of March. For early Cauliflowers we prefer small young plants in October, and enticing them on with sun heat and protection after March. When we had more time we used to have hoods made of straw, with four pieces of hazel rod to keep the square for the bottom of the glass, and these were easily lifted off and on.

As stated above, *damp* is the great evil to be guarded against as respects growing plants; in fact, now damp is the great enemy to all plants under protection, and in such changeable weather as much air as possible should be given to plants under glass in pits and frames by tilting up the sashes and not by sliding them.

Every hole and breakage in the glass now tells most injuriously, because such a breakage lets in the water that falls on the glass above it. Tilting up lights is by far the best mode of air-giving in all weathers; but sliding the sash is so much more easy in general, that it will be practised if not countermanded. Even in a cold pit in a cold day, tilting at the back does not fully expose the plants at the back, and the cold air rushing in is met by the warm air going out, and is thus mollified before reaching the plants. This is of still greater importance when the plants are growing in artificial heat. In hotbeds heated by dung, we have known numerous disasters arise from carelessly sliding the sash down over a lining of rank dung in front. The fumes of the dung were intercepted by the overhanging sash, and passed in among the tender plants in the bed.

For Lettuce, Endive, Sea-kale, Rhubarb, and Mushrooms, see remarks a few weeks back.

Mushrooms.—Our first piece in the lean-to house is doing very well, though it became rather cold after spawning, but helped, no doubt, from being on a shelf, and some warm droppings placed beneath it. The second piece is beginning to show. A third large piece became rather hot after spawning, and was carefully watched. If it had become hotter we would have taken out the spawn. Throwing a little earth over the surface, and beating firm down, arrested fermentation; and finding the spawn was still safe, and the heat remaining uniform, this piece was also earthed-up, well beaten, watered on the surface, and a clean spade drawn firmly over it, to leave a smooth surface. We have frequently stated how to obtain moderately thin Mushrooms for frying, and thick fleshy ones, that are with difficulty cooked up to the centre, but are excellent for chopping up.

From what we can learn of many of our new beginners' failures, they are chiefly owing to the spawn being put in material too wet or too hot. The temperature mentioned at page 416 may be considered in every way safe. If the material of a bed is very dry, the Mushrooms will be poor; if wetter than desirable, we wrap the spawn in a good handful of dry litter. Much shaking and working of the material, if at all rich at first, causes it to part with a large proportion of its nourishing qualities. We have never had better Mushrooms on shallow beds, than when we brought the droppings every day from the stable, and began making the bed at once, adding to it every day. The layers were so thin, that, when moderately beaten, they never heated violently.

FRUIT GARDEN.

Proceeded, as opportunity offered, with pruning fruit trees, making arrangements for planting what could not be done earlier in the autumn, and watered with warmed water some trees planted at the end of October in a Peach house, which we shall want to start presently, merely keeping the frost out on account of the other plants in the house. In the very changeable weather—rainy, frosty, foggy, and snowy—we were glad we had all our Strawberry plants under some kind of protection from excessive wet and severe frost.

We have had an inquiry from an esteemed correspondent,

who is anxious to grow a few small trees of *Peaches and Plums in pots* in a small glass house which he has put up; and he thinks he could manage very well, only he cannot have his plants until the middle of January, and he must, from the expense of carriage, have them sent without their pots, and as light as possible to be safe. He therefore dreads he will lose a season from not having them sent in the autumn, as Plums and some Cherries must be lifted out of the ground, though furnished with fruit buds. Of course it would have been better if such plants had been potted early in autumn—better still if the plants were sent in the pots in which they had grown the previous summer, so as to be well established. If, however, he obtain good plants even later than stated, there is no reason to despair, as he is merely going to place them ultimately in an unheated house. These simple modes which we have followed will almost be sure to be attended with success. The first point as respects trees raised from the ground depends much on the fruit-tree merchant and those he employs. Such trees should be raised carefully—not pulled up—the roots damped with the rose of a watering-pot, and then packed firmly in damped litter, the tops, of course, being merely secured in the usual way. Such trees, when they arrive, should be potted, choosing pots merely large enough. If the roots are somewhat damp, proceed at once. If, notwithstanding the care taken in packing, the roots seem dry, and have little earth about them, place them for a few minutes in a tub of water at about 65°. In potting, pack the roots neatly, and firm the soil well. Before this is done, or whilst doing so, make up a rough simple hotbed, say from 12 to 15 inches deep of litter, tree leaves, or any rubbish that will raise a gentle heat of from 75° to 80°, and in this plunge the pots to the rim, with a few leaves or some litter over the surface. Watch the bed, and if the heat rise higher than 80° raise the pots, or pull the material of the bed away from their sides. If it fall to 60° or 65° turn it over, or merely add a few inches more to the surface. Suppose you do this in the middle of January, the bed will have come down to much the same temperature as the earth will be in your unheated house by the first or second week in March, and if these points have been attended to, on examining the pots you will find fine, vigorous, fresh roots before even there be much appearance of growth in the top of the trees.

One great element of success is thus gained—the roots are made to move in advance of, and not after the motion of the buds. The great advantage of autumn planting and of autumn potting in such a case as this, is that the heat in the ground acts much in the same way as the above slight hotbed would do. Planting, and in such a case as the above, potting in spring in the usual way, exposes the plant to the liability of having the buds excited by the growing heat of the season, whilst the roots have scarcely begun to move to sustain the necessary correlative action.

We allude to this helping with a mild hotbed the more prominently, as the plan will succeed with all shrubs, Roses, &c., and even herbaceous plants that are lifted from the ground to be forced. Two things are essential to success—first, the heat given should never be so high as to weaken the roots, and though, in cases of forcing, the roots when growing will not suffer from going into a temperature a little higher under glass, when no forcing is attempted the temperature in the bed should have fallen as low as the earth of the house to which the plant is taken, so that no check may be given to the fresh roots in moving them from a warmer to a colder position.

One other condition is necessary to success, so far as the occupiers of this open-air slight hotbed are concerned, and it is that excessively bright sun should be kept from the shoots and buds with a little shading—say evergreen boughs, but in all dull and coldish weather, the freest exposure should be given, as the later in such circumstances the flower buds open, the more certain will you be of a crop the first season.

The retarding of the swelling and opening of the buds will be helped by free air; and this will be promoted still further if the tops be whitened with limewash, which will fall off partly as the buds swell. We have not yet, as a body of observers, made so much of *colour* as we might have done. Some time ago a philosophical enthusiastic amateur gardener was next to horrified at seeing a row of bush Pear trees as white in the beginning of March as if covered all over with snow, partly for the purpose of deterring birds from the buds, as white is rather distasteful to them. "Why, Mr. F., you will burn and scorch up buds and shoots alike! I lately had all the leaves of my Cucumber plants near the top of that steep-roofed lean-to house parched and scorched up, because, for the sake of neatness, I could not get the wall made too white. Nothing could stand the terrible heat of that white wall, and see if you do not be served in a similar manner." Our clever friend for a moment massed together in one things that differ. It was not the heat of or on the wall, it was the reflection of the heat of the sun from it, and that in a confined atmosphere, which did the mischief. Our trees would actually be kept cooler than if robed in their natural dark brownish livery; the reflection of the heating rays from them would only help to warm the neighbouring atmosphere.

We want more facts and proofs as to how far this may act in the neighbourhood of fruit trees in the open air or against walls. If our ideas should be right, it is just possible that two or three lines of the "Science and Practice of Gardening," which we recommend to all who aspire to be something more than routine workmen, may need a little modification. Be this as it may, the matter is sufficiently important to refer to again, and perhaps to justify this seeming digression that has come to our pen without previous consideration, the reason, no doubt, why so many digressions had better have remained unpenned. Be this as it may, the season has proved to us that circumstances must regulate rules and operations. However beneficial autumn planting, in this neighbourhood it could not have been done to any extent, owing to the dryness of the ground and the scarcity of water.

ORNAMENTAL DEPARTMENT.

The frosty weather, and being engaged in ice-collecting, gave us a good chance for practising the principles referred to in writing of Cauliflowers. Everything in cold pits, as Calceolarias, Roses, Cinerarias, Verbenas, &c., has been left to itself for four or five days, the covering remaining on night and day. We know the plants are cool enough not to grow, and when uncovered the long night will be to them like an ordinary one. It is very different when there is heat enough shut in to stimulate extension, if not true growth; then light for a time should be given.

Having lately referred to planting bulbs and necessary preparations, we shall leave other matters to refer to the in-door treatment of

Bulbs.—Potted a second lot, and set the pots on a dry place, on ashes covering a layer of lime to prevent worms rising; then covered over with finely-sifted leaf mould, and surfaced with fine coal ashes. Some old boards were set round them, enclosing the bulbs as it were in a box, and a cordon of tar 2 or 3 inches wide was run all round the box, so as to keep rats and mice at a distance, for if they were left alone they would soon make havoc of Crocuses, Tulips, &c. The first lot of bulbs we shall place in a sweet hotbed, when the pots are more crammed with roots. Frequently, when we have obtained bulbs late, we have brought them into flower early by the following mode:—After potting, we have plunged the pots up to the rim in a mild hotbed, with a bottom heat averaging from 75° to 78°, and a top heat in the frame or box of from 45° to 50°, by merely covering with glass, and leaving air on at top and bottom, in mild weather. The top heat was kept low so as not to bring up the flower stalk at all until the soil was crammed with roots. This plan in an emergency will give an advance of several weeks. When bulbs can be potted early, there will be no necessity for it. Of all bulbs, Crocuses will least bear forcing, and they should be potted rather more deeply than other bulbs. The Large Yellow, and the finer varieties, do very well in pots, and stand more upright and robust when the corms are covered at least 1 inch. Under no circumstances will they be better of hotbed treatment, such as a Hyacinth would delight in. Nowhere will they do better than in the window of a cottage, where the heat of the room is not too high, nor the air too close. With the Large Yellow, fine purple, blue, white, and striped kinds, an effective show may thus be made, and successions may be had for some time.

A few remarks, now, as to soil and potting. Bulbs will flower with but little assistance, merely from the support stored up in the bulb, but when so treated the bulbs would require years to recover themselves so as to bloom well again. Thus Hyacinths will bloom well in glasses with almost nothing but common soft water to help them, but such bulbs are more injured as respects the future than those grown and slightly forced in pots. Soil, therefore, is something, though not so particular a matter as many would insist upon. Any light, loamy, rich, sweet, soil will grow bulbs in great perfection. All worn-out soil should be avoided, and all that is clammy, wet, and sour. If a compost is to be made, the following is what

will answer well—three parts fibrous fresh loam, sifted through an inch sieve, one part drift or silver sand, one part sweet well-aired old cow dung or leaf mould, and if to be had one part, in addition, of small rough, not dust, charcoal. We think the charcoal gives a deeper green to the foliage, and permits of freer watering. When the flower stem is rising freely, weak manure waterings will give strength to the flower stem, and size to the flowers. When other soil was not to be had, we have potted in loam, with a third of sweet rotted leaf mould, but the sand, such as may be picked up in runs on the highway, makes all work better. All things considered, the compost can scarcely be too simple if light, sweet, and tolerably rich.

Now, as to potting and pots. When the plants are to be moved when in bloom, what are called 48's and 40's will bloom Hyacinths well, and the same sized pots will do for five Crocuses and three of the smaller Tulips. When very fine specimens of Hyacinths, &c., are wanted, the old-fashioned pots of the above size in width, but much deeper, are a great advantage, as the roots like to go down. In such deep pots the bulbs can be more deeply covered than in the common more shallow pots. Other things being equal, all these bulbs in pots will bloom and thrive better, if the bulbs be sufficiently sunk to keep them from free light and air. Even when the top of a Hyacinth bulb is exposed it will thank you to cover it, whether in a pot or glass, with a little green moss, and even that, though pretty, is inferior to the natural earth covering. These trifles attended to, if the bulbs are to be covered with ashes, &c., after potting, the more loosely and simply the potting is done the better it will be for the bulbs. All firming and squeezing the soil should be avoided. Many a fine Hyacinth bulb has been ruined by damping, or the incipient roots have turned up instead of going freely down, because the soil beneath the bulb was made immoderately firm. Proceed as follows, merely premising that the soil is in the proper state, neither wet nor dry—so wet that it will leave the impression of your fingers when you squeeze it tightly, so dry that the squeezed handful will fall to pieces when you lay it down on the potting-bench. Do not follow the common advice and fill such pots as the common size a third or so full of drainage. Give the roots all the room and earth you can. Place one convex piece of crock over the bottom of the pot, a scattering of smaller pieces over it, a little moss or chopped straw, and a dusting of soot, chiefly to deter worms, and the pot is ready. Place it on the potting-bench, and a trial or two will tell you exactly how much soil to put in to be ready for the bulb or bulbs, merely giving the pot after so filling a good stroke on the table to settle the soil, but not to firm it. With such treatment the top of a Hyacinth bulb should be on a level with the top of the pot, add more soil round the sides, and another stroke of the bottom of the pot on the bench will generally make that firm enough; if not, press it to the bulb a little with the fingers, but not downwards; a small cone of earth over the bulb completes the potting. When such pots, set in a bed, and covered with a weight of several inches of ashes, are moved to the forcing house, the bulb will be something like a quarter of an inch below the rim of the pot, and the pot will be crammed with healthy roots. When cottagers and householders merely pot a few, there is no necessity for placing them in a bed out of doors and covering them over for safety. Any cool dark place will do. In this case, though the earth should not be squeezed or firmed beneath the bulb, it will be necessary to firm it more at the sides, but not hard, and the bulb should be placed a little lower down. In their case, too, the bulbs will bloom all the better if the flower stems do not show much until the pots are filled with roots. Then, and and when the stems move, the sooner the pots are brought to and kept near the light the better. Many people would never have Hyacinths, Tulips, and Crocuses in bloom standing on mantelshelfs and out-of-the-way recesses and dark corners, if they knew what pain it gave to many of their visitors to see them subjecting the plants to a process of slow but sure decline. The pots, if placed in a bed out of doors, will generally need no watering. Those placed in cellars, cupboards, &c., must not be allowed to become dry; a moist soil, but not saturated, will encourage quick and free rooting.

As to glasses, when these are clear, clear water should be used, and fresh added as it evaporates. A little charcoal will keep it sweet. However, as it is easily done, fresh water of the temperature of the room may be given every week. The water should be soft. The base of the bulb should barely touch the water at first. In coloured glasses we have found weak clear manure water an advantage. After-treatment must be deferred, merely stating now that the chief reason why forced bulbs are much injured, is because, often from want of room, sufficient attention cannot be given to the foliage after blooming. For all plants that bloom early the foliage should be encouraged to perfect itself under glass, and then the bulbs would suffer little.—R. F.

COVENT GARDEN MARKET.—December 8.

Very little change can be noticed here, either in supply or demand, the general tone of the market having a downward tendency. The Potato trade continues dull.

TRADE CATALOGUES RECEIVED.

James Dickson & Sons, Newton Nurseries, and 102, Eastgate Street, Chester.—*Catalogue of Forest Trees, Conifers, Fruit Trees, Roses, Ornamental Trees, Plants, &c.*

Putz & Roes, Ferdinand Jüblke's successors, Erfurt, Prussia; London Depôt, Dick Radclyffe & Co., 129, High Holborn.—*Annual Trade Seed List.*

TO CORRESPONDENTS.

*** We request that no one will write privately to any of the correspondents of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely to The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

Flower Garden Bed (*Pa pas*).—As a bed of foliage your arrangement will look very well. In the plan we should prefer the Coleus to the Iresine, but both might be used, the Iresine filling the triangular spaces of the vandyking. We do not know the fungus by the description.

Local Flower Shows (*W. B.*).—We regret much that we cannot afford space for local flower shows. We have tried to make a selection, but no sooner did we do so than we had a crowd of reports, the writers of which joined in a chorus, "Our show was quite as good as that you inserted!"

Out-door Grapes.—In the Fruit-Committee report, November 18th, page 398, it should have been stated that Mr. Fenn ripened 342 lbs. of Grapes this year, instead of having made that number of gallons of wine.

Grapes Spotted (*J. G.*).—The berries of your Bowood Muscat are severely affected with "the spot," by which name gardeners speak of an ulceration of the Grape. It usually is occasioned by the roots failing to supply a sufficiency of sap to support the growth of the Vine and its

fruit. The roots should be kept warmer, watered with tepid weak manure water; and the surface soil removed and replaced by a richer soil. If the roots have descended into a cold ungenial subsoil, they should be raised to nearer the surface.

Protecting a Vine Border (*Amateur*).—We recommend the sheltering of Vine borders from rain from the time that the Grapes are ripe until the buds begin to swell, or from September to April, though if the Vines are started in February the covering should be removed by day when the days are mild and sunny, and replaced at night; and to admit of the border receiving moisture it should be uncovered during mild rains, but protected against cold deluging rains. In fact, the covering of the border is desirable up to May, during cold heavy rains and frosty nights.

Unripe Tomatoes (*Idem*).—We are not aware that these are of any use in an unripe state, but you may hang them in a warm and dry place, and they will in most instances ripen, and become fit for every culinary purpose.

Applying Soot to Fruit Trees (*Idem*).—In March you may sprinkle soot on the soil about fruit trees as far as the roots extend, and repeat the dressing in May. At each time the ground may be made quite black. After this it is best applied as a liquid manure, putting one peck to thirty gallons of rain water, well stirred-up before use. A good soaking of this in dry weather during summer would be very serviceable.

Vines in Pots (*Dorset*).—There is nothing on this mode of culture in the work you mention, but there is in "The Vine Manual," which you can have post free from our office if you enclose thirty-four postage stamps with your address.

Roses on Manetti Stocks (*Halcyon*).—"Your query, 'How am I to grow Roses on Manetti stocks planted a year ago?' is too general. My Roses on the Manetti stock, whether planted lately or years back, are treated thus:—They are tied to a stake, as they are open to the strong west and south-west winds. Round their base litter is now placed, and the soil is drawn over the litter like a molehill. This will preserve the roots and protect 3 or 4 inches of the wood. If the frost, which I expect will be severe in January, kill the upper portion of the wood, still the lower protected portion will break. In the spring the trees will be thinned out, cutting away all the weak wood, the strong shoots shortened, and the side branches cut to a sound plump eye. In summer, especially in hot weather, I keep the ground shallow-stirred over the roots, and deeply stirred between the rows, and I water copiously over the leaves, stems, and roots twice a-week. Orange fungus should be cut out, aphides killed by hand, and the trees should be well syringed. In February the molehills may be spread.—W. F. Radclyffe."

List of Roses (*Rosalind*).—Your list of thirty-eight Roses is so good that it is difficult to suggest much alteration. We should erase Lady Emily Peel, President Mas, Camille de Bernardin, Monsieur Woolfield, Souvenir de Dr. Jamin, Charles Rouillard, Louise Darzens, Alfred de Rougemont, Aimée Vibert, and instead of the two Mosses Laneі and Crested, we would grow one of M. Edouard Ory. This will leave ten places to fill up, in which we should plant Abel Grand, Antoine Ducher, Comtesse C. de Chatillant, Elie Morel, François Lacharme, Marguerite de St. Amand, M. Noman, Mdlle. Marie Rady, Marie Baumann, and Victor Verdier. There are, however, some other Roses which you ought to have if room can be found for them, or if any of these not discarded from the list are bad plants, as Duchesse de Caylus, Duc de Cazes, Duc de Wellington, François Louvat, Gloire de Vitry, La Brillante, Le Rhone, La France, Madame Clémence Joigneaux, Maréchal Vaillant, Prince Camille de Rohan, and Thorin. We are not quite certain whether the Rose named in the list as "Mlle. le Baronne Rothschild" is Madame la Baronne de Rothschild or Monsieur le Baron de Rothschild; the two names are rather puzzling, but Madame la Baronne is one of the finest Roses grown, a most beautiful satin pink, and ought to be in every collection.

Yucca Planting (*Sunny*).—The best time to plant Yuccas is in April or the beginning of May; but we have planted them from August to November successfully. They succeed best in a deep, well-drained, moderately rich, light loam, and in wet heavy soils are best grown on mounds or rockwork. Yucca aloifolia pendula is, perhaps, the tenderest of all the hardy kinds, and it rarely succeeds except in sheltered situations and dry soils, or in positions near the sea. It usually flowers in August. It does not flower very often, owing to the plant not obtaining a position warm enough to attain a sufficient size for flowering.

Chrysanthemums in a Greenhouse (*Idem*).—All the Chrysanthemums are hardy, and will succeed in the open ground with a little leaf soil or litter placed over them to protect them from severe frost. The duration of their flowers, however, is too often shortened by severe autumn frosts. Those you have in pots in the greenhouse may be planted out of doors after flowering, turning them out of the pots, or plunging these to the rim, and with a slight protection of dry litter in severe weather they will survive the winter. It is better to protect the plants by a frame, or place them in a warm sheltered situation for the winter.

Azalea Losing its Leaves (*C. A. G.*).—We do not think there is anything the matter with the plant. It is usual for Azaleas to lose part of their leaves at this or an earlier period, and some of the white kinds become almost leafless; but that does not affect their flowering.

Camellias for Out of Doors (*Constant Reader*).—Unless your situation is mild, and the soil well drained, you will not find Camellias succeed. They are best planted in summer after the growths are made, though plants well hardened-off may be planted in spring. Out of doors their treatment does not differ from that of hardy evergreen shrubs. Some of the hardiest are Alba plena, Bealii (Leeana superba), Donkelaari, Eximia, Imbricata, Monarch, Prince Albert, Reticulata, Striata, and Wilderi.

Sweet Jasmine Pruning (*Idem*).—The best time to prune is in spring before it begins to grow, cutting away the old wood and shoots that have flowered. All shoots not required for extension, or to fill-up vacant spaces, may be closely spurred-in to within one or two joints of their base. It is well, however, to leave some young shoots, as the flowers are finer from them than those borne by spurs. The flowers are produced from the points of the shoots of the current year.

Three Pear trees for a South Wall (*L. H.*).—Doyenné du Comice, Winter Nelis, and Ne Plus Meuris. They are late dessert Pears.

Methylated Spirit (*T. R.*).—It is sold by the druggists. It is applied by a brush to the branches on which the scale (Coccus) is fixed.

Rhododendron Stem Damaged (*W. T.*).—The standard Rhododendron Barclayanum with the wounds on the stem, "the bark off sharp and clean, without the wood being damaged," ought to be covered with clay well worked with about one-third of cow dung. Cover the wound thinly, and secure the whole with matting neatly tied on. It will prevent the wood from decaying by excluding wet, and will encourage the growth of the bark over the wounded part. The clay should be renewed as required, and in summer be covered with a little moss to keep it from cracking.

Weedy Lawn (*A Subscriber*).—You will gain little by paring-off the turf unless you have it deeply dug or trenched, afterwards picking out the deeply-rooted weeds, such as Dandelion. We would do this, and then apply the fresh soil as early as we could, so that it might have time to settle and become firm before spring. You may then level any inequalities, and having the surface in good working order, sow early in April as you propose. Anything that would kill the weeds in the old or new soil would injure the grass seeds.

Warm and Cool Greenhouse (*Devon*).—The greenhouse with a temperature of 35°, which we presume is the minimum night temperature, will be suitable for all kinds of hardwooded plants, Cinerarias, and Calceolarias, also Pelargoniums and many of the hardiest of the Cactus tribe, no water being given them except to keep them from shrivelling. The Lantanas, Solanums, Tecoma and Mimulus, with all kinds of bedding plants well rooted, and not recently potted, would be the better of the cool house rather than the warm one at 45°, if they be kept dry. The other house at a night temperature of 45° will answer for Eucharis and many cool stove plants—as Dracæuas, &c, they being kept sparingly watered. It is well to have in the warm house newly-struck Pelargonium cuttings, also newly-potted plants, until they become well rooted and established; then they should be removed to the cool house.

Wintering Fuchsias (*Idem*).—The Fuchsias will do well in the harness-room, keeping them from frost by a covering of dry hay wrapped about the pots, and covering the tops with mats or other protecting material. No water should be given beyond a little occasionally if required to keep the wood from shrivelling, and during mild weather only. If frost be not excluded the plants will die.

Late Tulips (*Tulips*).—Of your Tulips the following are good:—*Roses*: Vicar of Radford, Mary Lamb, Claudiana, Maid of Falaise, and Bion. *Byblœmens*: Lady Leicester, Chellaston Beauty, Maid of Orleans, and Duc de Bordeaux. *Bizarres*: Gold Cup, Duke of Devonshire, Solon, and Sir Joseph Paxton. Many of the others are sometimes good, but we have pointed out the best in your list. Your must rely on your own genius as to the crossing. They are sometimes grown in pots, but it is not advantageous. The price you name per dozen is very cheap. Those we have named are worth four times the money you have given for the whole.

Clivia nobilis not Growing (*Idem*).—The plant potted seven weeks ago will very likely not grow until spring. Keep the soil no more than moist during the winter. To do well, it requires a warm greenhouse. The kitchen window is much too dry for it, and the temperature too high and fluctuating. The sphagnum on the top of the pot would do as much harm as good. Do not use it.

Peperomia argyrea Treatment (*M. H.*).—It requires a temperature of from 55° to 65° in winter, and 65° to 85° in summer. Being a dwarf stemless species, it is best grown in a pan, well drained, and filled with sandy fibrous peat and sandy loam, in equal parts, torn in pieces with the hand, and used rather rough, charcoal in pieces from the size of a pea to that of a hazel nut, crocks broken small, and silver sand, of the last three half a part, the whole well mixed, using the finer portions for placing over the roots. When the plant is growing give it a moist atmosphere, and liberal supplies of water when it is growing freely, keeping it in a slightly shaded position. When not growing the soil should be rather drier. Avoid wetting the leaves, as they are apt to become disfigured if water stand or drip on them.

Billbergia iridifolia (*Idem*).—It is usual for the old stems and leaves to die down after flowering, young ones being produced from their bases. The old ones survive until the young growths are matured or far advanced, as in the case of the majority of Bromeliads.

Potting Violets (*Rush*).—The plants put into small pots ought to be shifted without delay into their blooming pots. The shift should not be large, say from a 3-inch to 4½-inch pot, or at the most a 5-inch pot. If already in 4 to 5-inch pots do not pot them, especially as you wish the plants to flower in January or February. In 3-inch pots they cannot be expected to do much, though with us they have succeeded well in that size of pot. A rich fibrous loam, light rather than heavy, with a little leaf soil and old cow dung, will grow them well. The proportion of four parts loam to one part of each of the other ingredients will do well. The runners which have formed since the plants were potted should be cut off.

Potting Heliotropes, Pelargoniums, Lobelias, and Salvias (*Idem*).—For winter-blooming the plants should not be repotted now unless they are in very small pots; then a slight shift would be advantageous. They flower more freely when the pots are filled with roots.

Cucumbers for a Trellis (*A Subscriber*).—All Cucumbers are suitable for trellises. Telegraph, Newton Hero, and All the Year Round are three of the best Cucumbers for winter or summer.

Decorative Greenhouse Plants (*Idem*).—We presume by decorative greenhouse plants you mean those which may be employed in-doors at times, which are of good close habit, and free-blooming. Acacia armata, A. longifora magnifica, A. oleifolia elegans, Bouvardia Humboldti, B. Leiantha floribunda, Chorozema varium nanum, C. cordatum splendens, Otaheite Orange, Correas Brilliant and Harrisi, Cyclamen persicum vars., Cypripedium insigne, Cytisus Atleeanus, C. racemosus, Hibbertia Reidii, Hydrangea japonica and its variegated variety, Kalosanthes coccinea superba, Linum trigynum, Monochætum ensiferum, Myrtle, Rhododendron jasminiflorum and Princess Royal, Solanum capsicastrum, Statice brassicæfolia, Vallota purpurea, and Witsenia corymbosa. Flowering plants of all the preceding may be purchased at a moderate price, and with herbaceous Calceolarias, Cinerarias, Pelargoniums, Primulas, Fuchsias, Violets, Deutzia gracilis, Dielytra spectabilis, and bulbs, you may keep up a succession of bloom throughout the year. Camellias, Azaleas, and Epacrises will not, of course, be omitted, as they are among the very best winter and spring flowering plants. A few fine-foliaged or variegated greenhouse plants are—Bambusa Fortunei variegata, Chamærops excelsa (perhaps the finest of all dwarf Palms), Dracæna australis,

Eurys latifolia variegata, Farfugium grande, Isolepis gracilis, Saxifraga sarmentosa, Sedum Sieboldi variegatum, Veronica Andersoni variegata, Yucca aloifolia variegata, and Y. filamentosa variegata. The above, with tree Mignonette and such half-hardy annuals as Gomphrena globosa, Amaranthus bicolor, Balsams, Celosia pyramidalis, with white, red, and orange plumes, and Thunbergia alata will keep a greenhouse quite gay.

Japanese Umbrella Pine (*Idem.*).—Sciadopitys verticillata, we think, would not succeed in an exposed south aspect 300 feet above the sea level, though, as you say Roses flourish beautifully, it would be well worth giving it a trial.

Burning Charcoal in a Vinery (*Devon*).—In an emergency we have used charcoal, coke, and cinders even in open braziers, when the alternative was hurting the plants with the products of combustion, or getting them more speedily and thoroughly injured by frost. All fuel will injure plants when burned in a stove without a flue. With prepared fuel, as when carbonic acid is neutralised, or to a certain extent consumed as it is formed, the danger is a little reduced, but not prevented. A small chimney would prevent any danger. We have a 3-inch pipe for a large stove; with prepared fuel, one not half the size might do.

Edging for a Bed of Roses (*Centifolia Rosea*).—Most people would be content without any edging round such a Rose bed. We think a ring of the dark China Rose, mixed with the miniature white, would look very well, and these would bloom well at from 8 to 12 inches in height. The Moss Saxifrage, as an evergreen close herbaceous plant, would also look very well, and so would a ring of Sweet Violets, as Double Blue, or even the Russian Blue.

Orchard-house Strawberries (*Amateur*).—See "Doings of the Last Week," page 402. The Strawberry plants in pots, the latter plunged outside, may be safe, but they are in greater danger than if they were inside the orchard house. In moving them to the orchard house (cold), and with no means of heating, we would not think of placing them there on shelves where you intend fruiting them. That would be merely avoiding one danger with the chance of running into another, as a sharp frost at any time for twelve or sixteen weeks hence, might be rather unsuitable for plants so situated. The plants would succeed much better set on the floor closely, all the leaves left on the plants, and packed in leaves or litter; and if the pots had no such packing, then there should be a mat or clean litter to cover them in severe weather. Before the plants are placed on the shelves, say in the middle of March, the old spotted leaves should be removed, and the surface soil cleaned off, and more fresh and rich compost added. We should put no plants in pots on shelves where we could not keep the frost out.

Pruning Apricot Trees in Pots—Stoves (*Idem*).—The Apricot trees in pots, not pinched back in summer, should not be severely cut back now, but merely a piece taken off the ends of the shoots, doing this after the buds had so far swelled that you could see how to cut with propriety. Severe pruning at once would be apt to cause you to lose the fruit, and in some cases the tree would also be injured. Next summer you can begin your particular training, and the trees would be all right the following year. We believe that Joyce & Nash's stove, and especially with their prepared fuel, will be useful in a severe frost to keep that frost from injuring the bloom, and especially before there is much wood growth. Open braziers of charcoal might also be useful in an extremity. Both stoves and braziers are dangerous to play with. Joyce's, we believe, would be quite safe with a small pipe going to the external air.

Selection of Fruits for a Garden (*W. B.*).—As your object is chiefly to have free-bearing, profitable, good selling sorts, we would recommend the following:—1, Prince Englebert Plum; 2, Dumelow's Seedling Apple; 3, Louise Bonne of Jersey Pear; 4, Cox's Orange Pippin and Small's Admirable Apples; 5, Denyer's Victoria Plum and Lord Suffield Apple alternately; 6, Cellini Apple and Beurré Bosc Pear alternately; 7, Williams's Bon Chrétien Pear. The Apples to be all on Paradise stocks, and the dwarf Pears on the Quince stock. For the slips at the end we would not recommend any other varieties than those we have just mentioned. When fruit is for sale, then the more there is of one sort the better it will sell. Variety is bad. Joséphine de Malines, Forelle, and Passe Colmar Pears, although good sorts, do not crop well, and Beurré d'Amanlis does not sell well; Beurré de Capiaumont is moderately profitable, and the same might be said of Dutch Mignonne Apple.

Ivy Leaves (*Foxgrove*).—We know of no special name for the variety you enclosed; it is one of the many forms taken by the leaves of the Hedera Helix folis-argenteis.

Dahlias (*A. Z.*).—Lilac Queen, Firefly, High Sheriff, nearly black, Leah, and Perfection. Fair Imogene comes near your other requirement, and there are plenty of lilac-tipped and shaded flowers.

Water from a Limestone Stratum (*J. C. Beale*).—Water passing through limestone is not good for many plants, especially Heaths, Azaleas, and other plants with very small delicate fibres. Unless drawn from a well or spring in the rock the water in limestone districts is little different from fresh-water streams generally, and is not inimical to plants; indeed we know places where good plants are grown with no water except that from limestone. Could you not have tanks to receive the rain water from the roofs of your buildings? It is the best for plants. The water from limestone may be improved by exposing it in a cistern for a few days before use.

Aloe Leaves not Developing (*H. D.*).—The plant has become stunted, probably from being placed out of doors whilst growing. Put the plant in spring, removing most of the old soil and the suckers, and place it in light turfy loam, providing good drainage whether in a pot or tub. Encourage it with a moist atmosphere and gentle heat, watering it sparingly at first, and increasing the supply with the growth. It would be well not to put the plant out of doors until July. The suckers should be potted when taken off. They will make good plants in a year or two, continuing them under glass for a time.

Seedling Cucumber (*G. Edwards*).—The specimen you sent to us, which you state is a cross between Edwards's Eclipse and Craig's Prolific, is very handsome and of a most useful size.

Winter Nelis Pear Unfruitful (*E. B.*).—We think your tree is too vigorous, and its roots have evidently passed into the subsoil. We would lift the tree at once, and place concrete under it to keep the roots from going down; and as inducements for them to remain near the surface apply top-dressings of rich compost in summer and give copious waterings in dry weather, restraining too-vigorous growth by comparatively close stopping. Probably in removing the tree you have placed it in a colder position than it was when it threw well, and that may be the cause of the fruit being small and cracked. Except in warm situations it does little good as a pyramid. It requires a wall, and is one of the very best Pears.

Management of a Sloping Bank (*Idem*).—We think the slope ought to be grass, and if it be twice the perpendicular height it would not only look far better than anything else, but would not be difficult to mow, very little more so than a level lawn. Ivy would do tolerably well; indeed, nothing excels it as a surface-covering. The small-leaved sorts are best. Plants should be put in, if of the small kinds 18 inches apart, and of the strong-growing sorts from 2 feet to 2 feet 6 inches apart. Plant in March, spreading the shoots over the surface, and securing them with pegs.

Tree Exposed to Smoke (*E. M.*).—No tree will flourish in the situation you describe. The Plane Tree endures smoke better than most others.

Border Edging Tiles.—We are informed that those mentioned on page 419 may be obtained from Mr. Hammill, brick and tile manufacturer, Bridgewater.

Celery with Solid Stem (*G. W. B.*).—Your Celery would "bolt"—that is, produce a flower stem, as soon as mild weather occurred. You plant too early, or do not keep it sufficiently watered, or grow it in too poor a soil.

Names of Fruits (*H. A. B.*).—1, Marmalade Pippin; 2, Ribston Pippin; 3, Braddick's Nonpareil; 5, Kingston Black; 6, Pearson's Plate; 7, Trumpington; 9, Winter Greening; 10, Yorkshire Greening; 11, Beurré Diel; 12, Catillac; 13, Lady's Finger; 14, Grey Leadington.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending December 7th.

Date.		Barometer.		Thermometer. Air.		Thermometer. Earth.		Wind.	Rain in inches.	General Remarks.

POULTRY, BEE, AND PIGEON CHRONICLE.

COMPETING COMMITTEEMEN.

"An Old Committeeman," writing in the Journal of Thursday last, is so temperate and persuasive, that were I dealing with individuals and not a class, I should be disposed to forego my objection. I readily admit that committeemen work hard, and spend liberally at their own show. It is, however, by no means a consequence that they should have the chance of a silver cup. My objection is founded upon a fixed principle that prevention is better than detection, and the conviction, which no one will deny, that if malpractices have not arisen from the custom of competing committeemen, the custom is open to dishonesty. What is true of committeemen is in the same measure true of the judges at poultry shows. I do not think that anyone will be rash enough to say that malpractices have not taken place. Common sense answers "An Old Committeeman's" assertion, that Birmingham being strong in two particular breeds, would never show the best birds of these breeds if committeemen were excluded from competition. Such a restriction might exclude from Birmingham as committeemen very celebrated exhibitors of those breeds; but, as committeemen, there are plenty of others capable of taking their

places. The withdrawal of a great name from Bristol as a committeeman would not pull down that show, and the owner of that name could well afford to pass without plucking another laurel there for his fame in Spanish fowls. I mention these cases because they are put forward by "An Old Committeeman;" but what is true of them is true of all.

"No Committeeman" writes also in the same number of your Journal; but beyond vague and general assertions he says nothing that needs mentioning, except, perhaps, the expression relating to committeemen "deprived of success, doubtless, greater at home than abroad." It is not easy to see fully the meaning of this remark. No man is a prophet in his own country; and unless a man happens to live in the home of a great show, I question whether he would not think the success of winning a cup greater abroad than at home. All England is open to success for committeemen who have really winning birds to show. They must, therefore, either give up all claims to praise for hard work and expenditure, or be content to win where others are working and spending money for them. There is need of reciprocity in more things than free trade.

I regret very much to find, from a notice in your Journal, that "Aliquis" is too ill to reply at present to his "opponents." Do not let us keep that word. For my part I shall meet him in all friendliness, not to oppose, but willing to go with him in anything that may conduce to the welfare of poultry shows.—Egomet.

CONSEQUENCES OF ASSOCIATING HENS OF DIFFERENT VARIETIES.

I am very much interested in the remarks of "Egomet" in "our Journal" about the consequences of associating together different hens of different colours, especially as only this season I have had instances in my own yard which at the time very much puzzled me. I had some White Cochins in a large pen; there were two hens and a cock, also there were running with them two Crêve-Cœur hens. I hatched several White Cochin chickens; they were principally pure white, but three were slightly spotted with black feathers, while one chicken was much spotted on the breast and back, and had a black tail. At the time I could in no way account for this, and imagined my birds had bred back, though I gave a high price for them and knew them to be pure; they have, moreover, quite recently taken a first prize. But now that I see some consequences mentioned in "our Journal" from the associating of different breeds, I begin to think that the reason why some of my White Cochin chickens were speckled was not from breeding back, but from the fact of Crêve Cœurs running with them. I had the chickens killed for the table as soon as large enough, for they looked so spurious along with their white brothers and sisters. I wish now I had waited for further results. I shall be curious to know whether more instances may be recorded.—R. S. S. Woodgate.

Your correspondent "Egomet," in the Journal of November 25th, in allusion to the subject of variation of colour in poultry, says, "It is pretty certain that white and black, and white and yellow, are interchangeable colours, whilst red remains unchanged." Is not white a sign in most animals of impurity of strain, or cross? The following experience for two seasons in my own small poultry yard may be not out of place on the subject of colour. My fowls are mostly Grey Dorking, a few Spanish, and two Buff Cochin-China hens. During one season a White Dorking cock, and the other season a Grey Dorking, has run with them. The progeny of the Cochin-China hens have been both seasons alike—white with small black tails, and a slight pencilling of black about the hackle and wings. They are all alike. Their Cochin characteristics are very decided, but their plumage mostly white; while, although the plumage of the hens is a uniform sandy buff, not a buff feather is to be seen in any of the pullets. The buff has changed to pure white.—C. M. Hughes, 7, *Paragon, Blackheath.*

THE POULTRY PENS AT THE SOUTHAMPTON SHOW.

In your number of the 18th ult. you make statements in your comments on the Southampton Show which are calculated to produce erroneous impressions, as well as to injure our reputation in connection with poultry shows. In the first place you say that "our representative asserts, that the whole number of pens left for Southampton a week previous to the day appointed for fixing them;" and then you say that "parties from the railway give the contrary version," which implies a direct falsehood. Now what our representative really did say was this, "that the portion of the pens, &c., which were too late, was consigned to the Southampton Show more than a week before the Show, which is correct. They were consigned from Accrington to Southampton before the order for the pens was given, but the rest, which arrived in time, were sent several days later, and we cannot believe the railway company in Southampton will deny the truth of the above. No one can regret more than we do the disappointment and inconvenience, as well as the anxiety, consequent on the late arrival of a portion of the pens, but everything was done that was possible, to make the best of the matter under the circumstances.

You suggest that a fine of £20 should be the penalty of non-fulfilment of contract, but we can assure you that £200 forfeit could not have altered the circumstances as far as the Show was concerned, as everything was done as far as possible to insure success in the arrangements, and it was not until too late to remedy the effect that the cause was discovered, which was that the railway company had neglected to collect the goods, until too late to reach in time. Again, you say that the cost of the pens in carriage from place to place is merely nominal; for your information we beg to inform you that the cost of the carriage of pens to Southampton was over one-third of the amount receivable for the hire of them.

We should not have troubled you with these remarks, but having invested considerable capital in exhibition pens, and never sparing expense or trouble to fulfil our engagements as far as lie in our power, we do consider it rather hard, as soon as there is a miscarriage, to charge the blame upon us in such an injurious manner. You are aware that as a rule the exhibitors of poultry seldom make their entries until after the closing time, which results in crowding all the arrangements into a very short space of time; and in order to prevent disappointment we have had to incur many additional expenses in getting the pens conveyed in time and fixed, and on several occasions we have lost money in doing so, although the cause was not ours. On one occasion we were as much as £10 losers; but we do not make a practice of publishing the shortcomings of secretaries or exhibitors, and beg that in future, should any misfortune occur, which we hope it may not, you will be as charitable as possible.—Turner & Son, *Sheffield.*

ORNITHOLOGICAL MONSTROSITY.

I see that I have very much yet to learn in poultry lore. A bird with four legs is a novelty. It is more, it is a curiosity. It may be more than this—namely, a fortune to a raree-showman. Fancy what might be done with it at the small price of one penny a-head, being as large as life and twice as natural.

A penny a-head! Really my head gets confused at the idea of a four-legged bird, and not only a four-legged one, but one *highly commended* in consequence at Birmingham. Surely some heads are not worth a penny. Will any poultry judge kindly tell me why this monstrosity was highly commended in a show which is held for the encouragement of poultry-breeding for use and for ornament? Was its deformed hideousness commended, or was Nature commended for an accident? Was its owner commended indirectly for his ingenuity in producing a malformation with which he had nothing to do? I shall really be glad of information, because if this is to be a rule of judging, I shall send the first infant I have without a nose to the first baby show that may offer itself; and I shall go in for breeding "ugly ducklings," in the certainty that I shall have commendations for them, which I have failed to receive for very perfect specimens of beauty at Birmingham and elsewhere.—Egomet.

[You will see by the report of the Birmingham Show in another page, that the highly commended card was misplaced, being intended for the Cuckoo Dorkings.—Eds.]

BIRMINGHAM POULTRY SHOW.

The twenty-first great annual Exhibition of poultry, &c., at Bingley Hall—a long career of well-deserved success! It is possible to have too much even of a good thing, and several times the question before the Council has been, How can we lessen the number of entries? Various expedients have been

adopted, but the cry was "Still they come!" This year the entrance money was augmented. It had the effect of slightly lessening the number of entries, but not enough to afford relief. There is not room in Bingley Hall for the numbers who show their confidence in the Committee, and their approval of the management, by competing for some of the many hundreds allotted for prizes. The two open spaces at the ends of the poultry bay are of great benefit; the gallery allotted to the Pigeons, the auction room filled with Ducks, and the Turkeys sharing part of the implement space, are all so many reliefs granted to the crowded poultry bay, but they are not enough. There is not room for the visitors, nor can they see the birds. Not only is nothing impossible to the Birmingham Council, but nothing seems difficult. We do not, therefore, hesitate to mention that which we heard frequently during the Show, that it would be better if the pens were raised higher from the ground. A rise of 12 inches would enable all the lower pens to come within the light afforded by the side lights of the roof, and visitors would be able to see the lower pens without effort.

There were three hundred pens of *Dorkings*, many of them of startling excellence. The increase in the weight of the hens still goes on; the cocks appear to be stationary. There would have been no difficulty in finding ten hens that weighed 100 lbs. Dorking cocks formerly ranked among the remarkable when they weighed 9 lbs., then they reached 10 lbs., since they have attained 12 lbs., but that seems their limit. Mrs. Arkwright repeated her success of last year; Admiral Hornby, Mr. Drewry, and Lord Chesterfield were among the successful, and reminded us of past years in the same building, where prizetaking has made their names familiar as household words. We were glad to see a second prize taken by Scotland. Mr. Anderson may be proud of his position and his exploit. The Silver Greys were better than we have ever seen. Fewer cocks were foul-feathered, and in both classes the winning birds might have been put in open competition with good hope of success. These are always aristocratic classes. The Ladies Dartmouth and Bagot, and Lord Bagot, were among the prizetakers. Although we shall hereafter have to speak of great improvements in classes, we do not think it was anywhere more visible than in the White Dorkings. Colour, shape, and weight were all in advance of former years. Cocks weighed more than 9 lbs., and hens 7 lbs. We deem it right to state here, at the beginning, our limits will not permit reference to every pen that deserves it; we are obliged to refer our readers to the published list of the prizes and commendations.

Two hundred and eighty pens of *Cochins*. These birds formed a show, and among the inducements to large entries figured four silver cups. We like the dissemination of prizes, and therefore our first mention in these classes shall be Mr. Zurhorst, of Dublin, who distinguished himself by taking the second prize for Cochin cocks. A very old amateur also deserves congratulation, Mr. Cattell took four prizes, including a silver cup. Mr. Taylor, of Manchester, took two silver cups. We were glad to note the return to these classes of an exhibitor, formerly well known; we allude to Capt. Heaton, who was successful. The Cinnamon and Buff classes were very meritorious. We found great size coupled with symmetry and good colour. A few pens showed a tendency to an old objection—viz., a dark mark at the end of the hackle feathers. It was always considered a disadvantage, if not a defect, and it would be a mistake if it were permitted to reappear. We can only say one word against the Whites, we mean the prevalence of vulture hocks. In all other particulars they were good, and we should like to see them more numerous. The Brown and Partridge were stronger in hens and pullets than in cocks. The former were many of them faultless; the latter were guilty of red feathers on their breasts. We know, experimentally, it is easier to breed them faulty than perfect, and many a cock that through chickenhood has been destined to great things, has failed almost at the last moment through a discoloured breast. The first-prize cockerel was in perfect health when judged, and dying on Monday morning.

Two hundred and thirty pens of *Brahmas*. What a reproof for those who once doubted the purity of this breed! Many of the birds in these classes were truly perfect—of enormous size, and perfect in symmetry and plumage. Fifty-nine pens among the Dark, and twelve among the Light, were deemed worthy of notice by the Judges. Mrs. Hart took two silver cups and many other prizes. We know no breed that is so largely disseminated over the United Kingdom as this is. The prizes went to England, Scotland, Ireland, and Wales. There is progress among the Light classes. Mrs. Williamson did wonders when she beat Mr. Pares in his own class. He made a good fight, being in three prize lists. We thought well of Mrs. Southard's birds, and Mr. Crook showed capital hens.

The *Malays* ought to show better in numbers and general merit. The "liberality of a few amateurs" enabled the Council to offer additional prizes. There were very good old birds; but in both the chicken classes the second prize was withheld. These entries were more numerous years ago than they are now.

It is satisfactory to turn from a decreasing to a very rising class: we allude to the French breeds. It may be safely said the *Crève-Cœurs* formed the best show of the breed there has yet been in England. Forty pens—large square birds, with glossy plumage, deep breasts, short legs—challenged the admiration of all who saw them. We do not believe they will ever equal the Dorking as a table fowl, but no one could look at them without seeing the meat was put in the right place, and that the offal would be light. We are glad again to note Mr. Zurhorst, of Dublin, was second. Every name printed on the prize-sheet deserves the honour, and all who appear there own first-rate birds. Fifty-seven pens of *Houdans*. These were as good as the Crève-Cœurs, and were faultless of their breed. The Hon. C. W. Fitzwilliam swept off all the *La Flèche* prizes. True, the competition was small, but the condition and size of the winners would have made their success easy in the teeth of more opponents. It would seem that Mr. Fitzwilliam has the gift of keeping these birds in condition; few can do it.

Seventy-nine pens of *Spanish*. We thought very highly of these, and noted in them a disposition to return to the old form—the long and smooth face preferred to the cauliflower surface. Mr. Lane deserves especial notice. The Hon. Miss Pennant, Messrs. Parkin Jones, and Rogers Bull richly merited their honours. We liked all the class, and admired the pullets more than the hens.

Black *Hamburghs* are beautiful birds, and as we looked at the classes we could but do homage to the skill and painstaking that had brought them from the large loose birds we recollect to the compact symmetrical birds that in 1869 would not suffer in comparison with their more gaily-plumaged brethren. The coal-black plumage, white ear, and red comb, make a perfect *ensemble*. The Golden and Silver were good, but we thought the former the best. There was one pullet in the prize pen pencilled to the tip of the tail as very few are. Some of the cocks were deficient in the bronzing of the sickle feathers. In many of the Silvers there was indistinctness of pencilling such as we did not see formerly; the prize pens were, however, very good. There were eighty-six pens of Spangled Hamburghs, and lots of good birds. We have never seen better than some of the prizetakers, and it was hard that some of the Golden highly commended had nothing better; but there was nothing for them. In these, too, we liked the Golden best. There is an accuracy in their "moons" that we do not meet with in the Silvers, and a richness of colour seems to belong to them.

What will be said to fifty-six pens of *Polish*? Their exhibitors are up and doing. Twenty-eight of these were Silvers. All the pens were good, and we look for a continuous improvement in every way.

We can only repeat of the next class that which we heard in the show—"The *Varieties* were various." The first prize went to a beautiful pen of Indian Game called "Bajra," the second to Silkies, the third to Andalusians. Some amusement was caused by a mistake. Two monsters were shown as four-legged Dorkings, and a highly commended card was stuck up on them instead of the Cuckoo Dorkings. Those who came in on Saturday evening noted it. Some were amused, and others, even among the press, were virtuously indignant. The appearance of the prize list on Monday morning satisfied all parties.

It is almost impossible to say much of the *Game*. They were perfect in all their classes. They were numerous. There is no detection of painting legs, or mending plumage, or pulling tails. We can only say every prize given was to the best of our belief well awarded, and every bird that received one deserved it. The Whites have disappeared, and the Blacks are few and far between.

The Sebright *Bantams* were not remarkable for numbers or quality; they were a bare average. The Whites were weak; the Blacks stronger, but not equal to past years. The "Variety Bantams" were better, and showed really good specimens. The Game Bantams were in greater force than ever, and the single cock class was in many respects wonderful. We have never seen them so even, so free from defect. We could but notice how few of these beautiful little birds are kept in the south of England.

Again the Aylesbury *Ducks* had to give way before the Rouen in numbers, weight, and merit. The successful Rouens weighed 18 lbs. 4 ozs., 17 lbs. 13 ozs., 17 lbs. 12 ozs., 17 lbs. 12 ozs., 16 lbs. 6 ozs., 16 lbs. 6 ozs.; the Aylesburys, 17 lbs. 12 ozs., 17 lbs. 7 ozs., 17 lbs. 2 ozs. White *Geese* weighed 50 lbs. and 42 lbs.; Old Grey, 57 lbs. 14 ozs., 53 lbs. 8 ozs.; young Grey, 48½ lbs., 46 lbs. 4 ozs. Single cock *Turkeys*, exceeding one year old, weighed 34 lbs., 32 lbs., 30 lbs., 29 lbs., 23 lbs.; birds of 1869, 23 lbs. 12 ozs., 23 lbs. 8 ozs; two hens, old, 32 lbs., 27 lbs. 4 ozs.; young, 28 lbs. 2 ozs., 27 lbs. 12 ozs.

We are gratified to add this Show was successful among the successful ones, the amount received reaching £1,412 1s. against £1,037 in 1868, £979 in 1867, and £648 in 1866.

Everyone connected with the meeting worked for success, and deserved it. Too much praise cannot be given to those who for nearly a quarter of a century, through good and bad report, have clung to and piloted this great undertaking. All interested in the poultry question are under obligation to Messrs. Wright, Matthews, Luckcock, Mapplebeck, Lowe, Shackel, Adkins, Sabin, and others, who have always been identified with it.

THE PIGEONS.

(From a Correspondent.)

The arrangement of placing some of the classes in the gallery and some in the poultry department was a mistake, and a great nuisance to the visitors. The Council availed themselves of the services of the four Judges who officiated so satisfactorily at the last Show, and certainly these gentlemen had this time made a better division of their work, as Messrs. Harrison Weir and Cottle judged the first seventeen

classes of the catalogue, and Messrs. Bidpeth and Esquilant the remaining twenty-six classes: but though the work was thus fairly apportioned, a better arrangement might have led to better results. I would suggest that the Judges, whoever they may be, cannot be qualified to judge all the classes they undertake successively: so instead of dividing the classes as arranged in the list, it would be much better if they divided them according to their knowledge of the merits of each class, as I think that Messrs. Weir and Cottle, who have judged the Carriers, should have also judged the Dragoons, especially as Mr. Weir's capabilities in the latter class are widely acknowledged.

Now a word as to the comfort of the specimens. The pens were certainly better sanded—a matter to which I drew attention last year, but I beg to suggest, and I hope with the same success, that the feeding and watering cans should be hung outside of the pens, so as to prevent the birds roosting on them, and mixing their food with their excrements, causing them to have dirty beaks after the first day, besides injuring their health.

Of *Almond Tumblers* there were seven entries. These were worthily represented in points, but not in quantity. Mr. Fulton was first with a very beautiful pair: Mr. Ford second with a pair not well matched, the hen being a rather inferior bird: Mr. Fulton third.

Pouter Cocks. Red.—Of these there were ten entries. Mr. Jones was first with a good bird, very slender, and long in the leg: Mr. Fulton second with a good bird. *Hens.*—Nineteen entries. Mr. Gresham was first with a rather small but very showy bird: Mr. Sturgess second with a nice bird: Mr. Stewart commended with a far superior bird to either in every point. The whole of the birds in these two classes were rather bad in colour, the most with splashed tails, &c.

Pouter Cocks. Blue.—Nine entries. Mr. Horner took the first prize and silver cup with a good bird 20½ inches in length, and perfect in marking, colour, and shape: Mr. Gresham was second with a bad-shaped bird: Mr. Gamon highly commended with the King of the Blues, which was far superior to the second-prize bird. *Hens.*—Seven entries. Mr. Fulton was first with a nice hen, but bad in colour: Mr. Gresham second with a good hen.

Pouter Cocks. Black.—Five entries. Mr. Gresham was first with a nice bird, good in all points but colour: Mr. Stewart second with a good specimen. *Hens.*—Three entries. Mr. Stewart was first with a grand hen: Mr. Fulton second with a good bird in bad condition. It is rather remarkable that in these two classes Mr. Stewart took two prizes with the two birds that were disqualified last year for being dyed, "but on close examination they do not appear to be varnished now."

Pouter Cocks. White.—Thirteen entries. Mrs. Ladd was first with a rather small bird, but very showy, in bad condition: Mr. Harvey second with a long-feathered bird, but short in leg: Mr. Fulton commended with a good bird in bad condition. *Hens.*—Sixteen entries. Mr. Fulton was first with a hen far too heavy: Mr. Rose's second-prize hen was grand in shape, style, and condition. The Whites were very good classes, numbering twenty-nine pens, by far the best in the Pouter classes.

Pouter Cocks, any other colour.—Eight entries. Mr. Rose was first with a perfect bird, but Mr. Fulton's second was rather inferior. *Hens.*—Six entries. Mr. Rose was first with a grand Yellow hen: Mr. Fulton second with a good-coloured hen, but of bad carriage.

The whole of the Pouter classes numbered eighty-six entries, being an increase of fifteen over last year: still the Committee ought to receive much more support to justify the liberal amount—£30, they give in prizes to Pouters, which is rather too partial.

Jacobins. Red or Yellow.—Twenty-two entries. Mr. Williams was first with very good Yellow birds, but the cock was rather too coarse. The same exhibitor was second with a fair pair of Reds, but not good in colour, and not well matched. Mr. Royds was highly commended for a pair of Yellows, good in all points, and the best pair in this class, which was the best ever seen.

Jacobins, any other colour.—Six entries. Mr. Royds was first with a faultless pair of Blacks: Mr. Williams second. This gentleman was most fortunate in taking three prizes, as the hen in each pen was marked the same as the Balds—that is, from halfway down the breast-bone they were white, which made them rather conspicuous, the cocks being perfect in this respect.

Barbs. Black.—Nine entries. Mr. Fulton was first with a very good pair in bad condition: Mr. Shaw second—the cock a remarkably good bird, the hen thin in beak and cross-beaked. Mr. Crossley was highly commended for a perfect pair, the best in the class, and quite healthy-looking, which is not often the case with the best specimens.

Barbs, any other colour.—Six entries. Mr. Crossley was first and second, the first-prize pair being a remarkable pair of Duns, the second very good Reds. Mr. Firth showed a good pair of Yellows.

Balds and Beards.—Eleven entries. Mr. Fulton was first, Mr. E. C. Bates second, Mr. South third, with good specimens. Mr. Choyce showed a pretty pair of Yellow Balds, which were highly commended, and Mr. Edge a good pair, though unnoticed.

Tumblers, Short-faced.—Eight entries. Mr. Fielding, jun., was first, Mr. Fulton second: Mr. Crossley's very highly commended were well worthy of a third prize.

Tumblers, any other variety.—Twelve entries. This class was most properly added for the first time in this Show, and I believe it would be more just to exhibitors if it were divided into two classes, so as to form a separate class for "Long-muffed Tumblers," which are a favourite variety with the numerous local fanciers. In this class Mr. Careless, Mr. Bradley, and Mr. Sproston exhibited some beautiful specimens, but the awards went to clear-legged birds. Mr. Hawley was first with Red Mottles; and Mr. Horner second with Yellow Mottles. The cock in this last pen was trimmed on the legs to remove partial muffs to make him match the hen.

Runts.—Seven entries. This class of the "heavy weights" was judged by weight, and Mr. T. D. Green deservedly took the silver cup and first and second prizes.

Antwerps.—Thirty-eight entries. Owing to the rapid increase in the entries of this variety, they were most properly divided into two classes—viz., Chequers and any other colour. In the *Chequer* class there were twenty-one entries. Mr. Ludlow was first with Blue Chequers, and Mr. Bulpin second with Red Chequers. In the class for *Any other colour*, Mr. Taylor was first, and Mr. Bradley second, both with Silver Duns. Both were excellent classes, and comprised many pens of high quality to the "initiated," who are very numerous. Among the Chequers were birds shown by Mr. Bradley, Mr. Copman, and Mr. Yardley, which, according to the numerous local fanciers, who can boast of introducing the "Show Antwerps," were more worthy of the prizes than the possessors of the honours. The first-prize birds were rather coarse in head, but splendid in colour and condition. The second-prize pair was much wanting in quality of head, and did not match in colour. Mr. Taylor's Silver Duns were a perfect match, but rather narrow in head: however, highly, they were sold for £3. Mr. Bradley's pair merited its place, though not in good condition. Mr. Yardley showed two birds which, "if a pair," would have deserved a prize, but the Judges were doubtful, and so passed them over.

Carrier Cocks. Black.—Sixteen entries. Mr. Horner was first with a very good specimen: Mr. Colley second, with, in my opinion, the best bird in the class, very narrow in skull, grand eye, and perfect carriage and colour. *Hens.*—Nine entries. Mr. Fulton was first and second with fair birds. Mr. Crossley's pen, 1995, was a far better bird than the second-prize one.

Carrier Cocks. Dun.—Eight entries. Mr. Hawley was first with a very good bird. Mr. Ord's second was rather coarse. Mr. Crossley again showed a far superior bird, which only had highly commended. *Hens.*—Eleven entries. Mr. Hawley was first with a grand bird, very large in eye, and good in carriage—in fact a perfect Carrier: and Mr. Crossley second with a fine hen. Mr. Colley showed a wonder for her age—seventeen months. This class was the best of the Carriers.

Carrier Cocks, any other colour.—Three entries. Mr. Fulton was first with a good specimen. This class was quite unworthy of any prize. *Hens.*—Four entries. Master H. A. Yardley was first, with a very good Blue hen, splendid in colour, but quite out of condition. This very specimen won only two or three years ago prizes in the Dragoon class!

Fantails. White.—Twenty-five entries. Mr. C. Bulpin was first and second with two good pairs: and Mr. Yardley third with a handsome pair, which to my mind should have been at least second. The majority were good, although there were a few pens of a common type which contrasted strongly with the prize birds.

Fantails, any other colour.—Nine entries. Mr. F. Graham was first with a pair of well-matched "true Blues, which well merited their position. Mr. Choyce was second with a pair of very middling Blacks, which did not deserve a place, the hen not being fit for showing, and the cock, if any other colour than black, would not be noticed. Mr. Yardley was highly commended with a pair of very good Blues, which, in my opinion, as in the other class, deserves a better position. The Blues in this class are of a much better colour than is usually seen in Fantails.

Trumpeters, Mottled.—Eight entries. Mr. Shaw was first with a good pair, but not well matched in markings: Mr. Harvey second; Mr. Firth, jun., highly commended: Mr. Taylor commended. In this class an extra first prize was awarded to a pair of birds accidentally not placed in the pen allotted to them till many hours after the birds were judged. I failed to discover the merit of the extra prize.

Trumpeters, any other colour.—Six entries. Mr. Firth, jun., was first with a superior pair of Blacks, well matched: Mr. Oates second with an excellent pair in capital condition: and Mr. Gamon highly commended.

Dragoons. Blue.—Seventeen entries. Mr. South was first for a pair of very coarse, broad-skulled, though good-coloured "young Carriers:" and Mr. J. Percivall second. There were several commendations, but evidently the best birds were unnoticed, and this was the opinion of the majority of the exhibitors. This was a good class.

Dragoons, Red or Yellow.—Seventeen entries. In this class some excellent specimens were exhibited. Mr. South was first with a beautiful pair of Yellows, pale in colour, yet in back and thigh uniformly good; they were worthy of their place, as the hen especially was very beautiful. Mr. P. H. Jones was second. This was a great mistake, for they were a coarse, heavy-wattled pair, besmeared with grease, and in all respects unworthy of notice. This was an excellent class—a better I never saw. Mr. Bulpin showed a very good pair of Yellows. Mr. J. Thompson exhibited the best pair of Reds I have seen for some time. Mr. Ludlow showed a neat pair of Yellows.

Dragoons, any other colour.—Fourteen entries. Mr. Percivall was first with a good pair of Silvers. Mr. J. Edge second with two good birds, but ill-matched. Mr. Allsopp unquestionably, although un-

noticed, exhibited the best pair of Silvers. There were several pens of White, all of which were inferior birds. In my opinion there is a standard wanted in the Dragoon breed, both for judges and exhibitors, as there was a very wide difference in the character of the successful birds, strongly proving the want of an acknowledged standard on the part of the judges, and the want of a guide for fanciers.

Owls, Foreign.—Six entries. Mr. F. Crossley was first with a very pretty pair of Whites; Mr. Fielding second; and Mr. S. Shaw highly commended. Mr. S. A. Wyllie showed a good pair in perfect condition.

Owls, English.—Nine entries. Mr. J. W. Edge was first with a very good pair of Whites, the cock perfect in head and frill. Mr. C. Bulpin was second, good. Mr. J. Firth showed a good pair in bad condition. The Rev. F. Watson was highly commended.

Nuns.—Fifteen entries. Mr. W. Banks was first with a pair not quite perfect in flights; Mr. C. Bulpin second with some white flights cut short; Mr. Banks third; Mr. W. Croft highly commended for a pair with cut flights; Mr. Jones commended. Nearly all the birds in this class were deficient in black flights, and the rest of a leaden black colour. I discovered that out of two pairs of birds there were nearly twenty white flights cut short to make them show the black!

Turbits, Red or Yellow.—Fourteen entries. Mr. S. Shaw was first; Mr. Horner was second; Mr. Shaw highly commended. The pen from the last-named was of a beautiful yellow colour, shell-capped, and in excellent condition—in fact, worthy of the second honours.

Turbits, any other colour.—Mr. J. South was first; Mr. W. Banks was second; Mr. Yardley highly commended. Mr. Fielding, jun., was highly commended. Mr. Paget exhibited a pair of Blues with white bars, which if shown in the "Any other variety" class I believe would not have been passed.

Magpies.—Thirteen entries. Mr. P. H. Jones was first; Mr. J. Firth, jun., was second; Mr. E. Horner highly commended. Very good to all appearance.

Archangels.—Nine entries. Mr. C. Bulpin was first; Mr. F. Sale second; Mr. W. Underwood highly commended. Rather a middling class, as the most of the specimens were somewhat chequered. Mr. S. Wyllie exhibited a very pretty pair of Archangels in character, but with rather blue wings and black bars, which if shown in the "Any other variety" class would most likely have met with success.

Swallows.—Thirteen entries. Mr. E. Horner was first, and Mr. J. Watts second. A good class, most of the birds being artistically got up.

Any other variety.—Eighteen entries. Mr. Yardley was first with Satinettes in perfect condition, and with the pair which claims the honour of having won upwards of £67 in prizes! The same exhibitor showed two pairs of the same breed, which, though better in points, were not in good condition. One of the Judges pronounced them irresistible. Mr. G. Sturgess had an extra first prize for Swifts, anything but beautiful, but most remarkable for length of feather. Mr. Paget was second with Scandaroons, a most remarkable and uncommon pair of birds, nicely marked with good red. Mr. W. B. Tegetmeier had an extra second prize for White Pigmy Pouters, or "White Isabels." In my opinion size does not constitute a "new variety." Mr. Paget was third with Blue Frillbacks, very bad in shape of head and colour, but said to be something new! Mr. Draycott had an extra third prize for an unnamed pair.

(From a Correspondent)

At the auction, as reported last week, only one Houdan is mentioned as sold, Mrs. Wilkins' third-prize cock, which realised £2. This would not give a fair idea of the popularity of the breed. Mr. Quibell's first-prize cock at the Show was claimed at £10 10*s.*; Mr. Fox's commended cockerel was claimed at £5; and several other pens were claimed at prices varying up to £5 5*s.*

LEEDS POULTRY SHOW.

Although this year it was impossible for the Leeds Committee to appoint any other days for the Show than November 30th and December 1st and 2nd, and consequently it clashed with Birmingham and another show, they have good reasons to congratulate themselves on the unprecedented success of this year's meeting, for, combined with a marked improvement in quality, the number of entries was far in advance of that at any previous Show at Leeds. There is one improvement, however, which must be made a subject of consideration; the time allowed the Judges is not nearly sufficient for them to deliberate carefully whilst making their awards, particularly as the greater portion of even this short period is during the full access of the public, so that the Judges have to make their way as best they can among anxious and often very interested visitors, and the decisions are consequently delayed.

A few pens of the *Game* fowls were very good, but, as might be expected, most of our greatest breeders of Game were exhibiting at Birmingham. The *Dorking* chickens were indeed a good class, but deformity in the feet of several of the old birds was a great drawback. All the *Spanish* were superior, chickens taking the silver cup for these classes. *Cochin-China* fowls were scarcely up to the mark: and the *Brahma* classes gave evidence that the best specimens had been culled for Birmingham. The *Hamburghs* were the glory of the Leeds Show. Every class was well filled, and the time and consideration devoted by the two Judges in awarding the silver cup expressly for Hamburghs, showed that their duty was a most anxious one. It was said that on this occasion nearly a dozen pens of Hamburghs that had at one time or another previously taken cups, were in competition. The selling class was unusually good, and a fair proportion of pens changed hands. *Game Bantams* were a fair group, but a general "trimming" threw out several good pens. *Turkeys* and *Geese*, as well as *Ducks*, were excellent. The show of "dressed" poultry was also excellent, but in all such cases, whatever description of bird it may be, the bird should be shown simply plucked and tied, and cut, as was the case at Leeds, drawn, and in some instances even larded ready to be put to the fire.

Pigeons formed large classes, and many of the very best birds in the kingdom were on view.

The entry of *Rabbits* was one of the marked features of the Show: among them was a lop-eared animal which seemed to have hosts of admirers, for the ears were so wonderfully developed that we were told they were carefully measured, and proved to be 22½ inches long, by 5 inches in width.

The weather was cold, and the frost rendered the ground so slippery as to prevent horses travelling, but the visitors were numerous, and congratulations as to the annual improvement of the Society were general.

Game Cock (Any description).—1, W. Spencer, Haworth. 2, W. H. Robinson, Keighley. 3, E. Winwood, Worcester. *hc*, J. Firth, Chatsworth, Bakewell; T. Dyson, Halifax; H. M. Jubau, Hull.

Game (Black-breasted Red).—1, J. Wilson, Calverley. 2, J. Firth. 3, W. Boyes, Beverley. *hc*, J. Barrow, jun, Kendal. *Chickens.*—1, E. Aykroyd Bradford. 2, W. Spencer. 3, J. Barrow, jun. *hc*, W. Spencer, Haworth H. Jowett, Idle, Leeds. *c*, J. W. Thompson, Southowram, Halifax.

Game (Brown-breasted and other Red, except Black-breasted).—1 and Cup, F. Sales, Crowle. 2, H. Hatton, Cleckheaton. 3, G. J. Robinson, Kendal. *Chickens.*—1, J. Smith, Bradford. 2, W. Johnson, Idle. 3, F. Sales. *hc*, J. Barrow, jun. *c*, J. Firth.

Game (Duckwings).—1, H. C. & W. J. Mason, Drighlington. 2, E. Aykroyd. 3, W. Boyes. *Chickens.*—1, W. J. Cope, Barnsley. 2, H. W. Mitchell, Moseley. 3, J. Wilson, Illingworth.

Game (Any other variety).—1, H. C. & W. J. Mason. 2, G. & C. Ferniss, Accrington. 3, J. Sunderland, Halifax. *c*, G. Pounder, Kirby Moor Side, York. *Chickens.*—1, H. C. & W. J. Mason. 2, J. Firth. 3, W. English, Pickering. *hc*, G. & C. Ferniss, Accrington.

Dorkings (Any colour).—1 and Cup, E. Maud, Middleton, Leeds. 2, J. White, Warlaby. 3, J. Stott, Healey. *hc*, J. P. Newton, Kirby-in-Cleveland; T. Briden, Earby, Skipton. *c*, W. Bearpark, Ainderby, Northallerton. *Chickens.*—1, T. E. Kell, Wetherby. 2, Mrs. Arkwright, Sutton Scarsdale. 3, L. Patton, Taunton. *hc*, T. E. Kell; W. H. King, Healey, Rochdale; J. J. Waller, Kendal. *c*, Wormald, Scoby, & Co., Kirby Moor Side; E. Sutton, Plas Wilmot, Oswestry.

Spanish.—1, Hon. Miss E. D. Pennant, Penrhyn Castle, Bangor. 2, W. and F. Pickard, Thorner. 3, J. Thresh, Bradford. *c*, T. & E. Comber, Warrington; J. Garnell, Bradford. *Chickens.*—1 and Cup, H. Beldon, Bingley. 2, Hon. Miss E. D. Pennant. 3, Tonkin & Tuckey, Bristol. *hc*, Birch & Boulter, Sheffield; T. & E. Comber. *c*, J. Lillitoe, Wolverhampton.

Cochin-China (Cinnamon and Buff).—1, W. A. Taylor, Manchester. 2, W. Massey, Spalding. 3, J. Berry, Sheffield. *Chickens.*—1 and Cup, W. A. Taylor. 2, C. Sedgwick, Keighley. 3, T. Stretch, Ormskirk.

Cochin-China (Any other variety).—1, W. A. Taylor. 2, T. Stretch. 3, Mrs. R. White, Sheffield. *Chickens.*—1, C. Sedgwick. 2, W. A. Taylor. 3, G. Calvert, Darlington. *hc*, H. Crosley, Broomfield, Halifax; G. H. Proctor, Durham; G. Calvert, Darlington.

Brahma Pootras (Any variety).—1, Hon. Miss E. D. Pennant. 2, E. Leach, Rochdale. 3, J. H. Pickles, Southport. *c*, W. Whiteley, Sheffield. *Chickens.*—1 and Cup, W. Harvey. 3, Hon. Miss E. D. Pennant. *hc*, Rev. E. Alder, Etwall Vicarage, Derby. *c*, E. Leach.

Hamburghs (Gold-pencilled).—1, H. Beldon. 2, S. Smith, Northowram. 3, J. Walker, Birstwith. *Chickens.*—1, W. J. Harker, Cottingley. 2, J. Walker. 3, H. Beldon. *hc*, W. R. Park, Abbotsmeadow, Melrose; S. Smith, Northowram, Halifax. *c*, B. Bee, Goornagh, Preston.

Hamburghs (Silver-pencilled).—1, H. Beldon. 2, Duke of Sutherland. 3, J. Walker, Birstwith. *Chickens.*—1, B. Longbottom, Bingley. 2, J. Walker. 3, H. Pickles, jun., Earby. *hc*, H. Smith, Keighley; W. R. Park; Duke of Sutherland, Trentham. *c*, J. Mitchell Keighley.

Hamburghs (Gold-spangled).—1, T. Blakeman, Tettenhall. 2, T. Walker, jun., Denton. 3, T. Dean, Keighley. *hc*, W. Driver, Keighley; H. Beldon. *c*, Mason & Walker, Denton, Manchester. *Chickens.*—1 and 3, J. Ogden, Hollinwood. 2, J. Chadderton, Hollinwood. *hc*, J. H. Booth, Upperthong, Holmfirth; H. Beldon; J. Rollinson, Lindley, near Otley; T. Blakeman, Tettenhall, Wolverhampton; E. Brierley; Mason & Walker. *c*, J. Buckley, Taunton, Ashton-under-Lyne; T. Boulton, Hanford, Stoke-on-Trent; Duke of Sutherland.

Hamburghs (Silver-spangled).—1, H. Beldon. 2, Mrs. Flynn, Stoke-on-Trent. *Chickens.*—1 and Cup, W. Bairstow. 2, D. Lord, Staeksteads. 3, H. Beldon. *hc*, Ashton & Booth, Mottram; W. Bairstow. *c*, A. Tair bourne, Todmorden; H. Pickles, jun.; G. & C. Duckworth, Accrington.

Hamburghs (Black).—1, C. Sedgwick. 2, D. Lord. 3, H. Beldon. *Chickens.*—1, T. Walker, jun. 2, C. Sedgwick. 3, Mason & Walker. *hc*, J. Greenwood, Keighley; D. Lord; Mason & Walker; W. Green, Keighley; J. Smith, Gilstead, Bingley.

Polands (Any variety).—1 and 2, H. Beldon. 3, T. & E. Comber, Warrington. *hc*, G. Boothby, Louth; J. S. Senior, Batley Carr, Dewsbury. *Chickens.*—1, J. S. Senior. 2, J. Batty, Holmfirth. 3, T. Dean. *c*, H. Bowker, Keighley; G. Boothby; W. Silvester, Sheffield.

Farmyard Cross (Any variety).—1, C. Layland, Warrington. 2, Mrs. J. Cross, Brigg. 3, W. Rinder, Leeds. *hc*, S. Ingham, Headingley R. Lott, Woodmansey, Beverley.

Selling Class.—1, J. J. Berry, Sheffield. 2, W. Leach, Oldham. 3, H. W. Illingworth, Idle. *hc*, H. W. Illingworth; W. A. Burnell, Southwell

Notts; E. Shaw; W. J. Cope, Barnsley; J. S. Senior; G. Calvert; J. P. Booth, Silsden. *c*, A. Aldersley, Sunny Bank, Keighley; Barker and Charnock, Illingworth, Halifax; W. Johnson, Idle, Leeds; F. Greenwood, Rochdale.

Bantams (Black).—1, S. S. Mossop, Long Sutton. 2, J. Walker, Halifax, 3, J. Waddington, Guiseley. *hc*, H. Draycott, Humberstone, Leicester; S. Rhodes, Normanton; H. Beldon; S. & R. Ashton, Mottram; Hudson and Burnip, Epworth. *c*, S. & R. Ashton; R. Youll, Sunderland.

Bantams (White).—1 and 2, S. & R. Ashton, Mottram. 3, E. Winwood, Worcester.

Game Bantams.—1 and Cup, W. Newsom, Holbeck. 2 and 3, J. Crosland, jun., Wakefield. *hc*, J. Crosland, jun. *c*, J. L. Oxley, Roundhay, Leeds; F. Steel, Stamp Cross, Halifax; S. Smith, Northowram, Halifax; J. C. Taylor, Oatlands, Leeds.

Bantams (Any other variety).—1, T. C. Harrison, Hull. 2, J. Walker, Halifax. 3, Mrs. Woodcock, Leicester. *hc*, Mrs. Arkwright, Sutton Scarsdale, Chesterfield; S. H. Stott, Rochdale.

Turkeys.—1, S. H. Stott, Rochdale. 2, A. Guy, Grantham. 3, E. Leach.

Geese (White).—1, Mrs. Braithwaite, Stokesley. 2, E. Leach. 3, Rev. G. Hustler, Stillingfleet Vicarage.

Geese (Grey and Mottled).—1, S. H. Stott. 2, E. Leach. 3, Rev. G. Hustler. *hc*, Lord Wenlock, Escrick Park; J. White, Whiteley, Netherton, Wakefield; J. Pitts, Drighlington.

Ducks.—*Aylesbury*.—1, S. H. Stott. 2, W. Stonehouse, Whiteley. 3, E. Leach. *Rouen*.—1, J. J. Waller, Kendal. 2, E. Leach. 3, J. White, Whiteley, Wakefield. *c*, H. Crossley; H. Dowsett, Pleshey, Chelmsford. *Any other Variety*.—1, A. & J. Trickett, Manchester. 2, T. C. Harrison. 3, O. Nussey, Headingley. *c*, F. E. Schofield, Morpeth; S. & R. Ashton.

PIGEONS.

Carriers.—1, G. C. Holt, Lawton. 2, J. C. Ord, London. *hc*, J. C. Ord; F. J. Leach.

Pouters.—1 and Cup, for best pen of Pigeons shown, W. Harvey, Sheffield. 2, E. Horner, Harewood. *hc*, C. Cowburn, Calls, Leeds; C. Cockton, Middlesbrough.

Tumblers (Short-faced).—1 and *hc*, W. Harvey. 2, J. Hawley; H. Yardley.

Tumblers (Any other variety).—1, J. Hawley. 2, F. Steel, Stump Cross. *hc*, J. Rollinson, Lindley, near Otley; F. J. Leach; E. Horner.

Owls.—1, J. Fielding, jun, Rochdale. 2, J. Crosland, jun. *hc*, W. C. Dawson, Otley.

Fantails.—1, E. Horner. 2, W. Harvey. *vhc*, W. R. Park. *hc*, J. C. Ord. *c*, J. Hawley; J. F. Liversedge, Newark-on-Trent; H. Yardley.

Barbs.—1, J. Fielding, jun. 2, W. Massey, Spalding. *hc*, J. Fielding, jun.; C. Cowburn.

Turbits.—1, E. Horner. 3, F. J. Leach. *hc*, F. Easten, Hull; F. S. Clayton, Bradford. *c*, J. C. Ord; R. Wilson, Thirsk.

Jacobins.—1, T. C. & E. Newbitt, Epworth. 2, J. Thompson, Bingley. *hc*, E. Horner. *c*, J. Hawley; C. Cowburn; E. Horner.

Trumpeters.—1, J. Hawley. 2, E. Horner. *hc*, J. C. Ord. *c*, A. A. Vander-Meersch, Forest Hill; — Robinson, Wakefield; J. S. Senior; W. Harvey.

Nuns.—1 and 2, F. Easten, Hull. *hc*, F. E. Thompson, Hull.

Dragoons.—1, T. Smith, Keighley. 2, W. Campsey, Beverley. 3, J. C. Ord. *hc*, T. Lambert, Silsden, Leeds; W. Markland, Dean, near Bolton; J. Walters, Derby; J. Mitchell, Moseley, Birmingham. *c*, J. Hawley; J. Lister, Keighley; J. S. Senior; H. Yardley.

Antwerps.—1, C. Anton, jun. 2, W. Harvey. *hc*, Mrs. Arkwright; J. Crosland, jun.; J. Thompson; H. W. Mitchell, Moseley, Birmingham.

Magpies.—1, J. T. Lishman, Girlington. 2, W. C. Dawson. *hc*, J. C. Ord; F. J. Leach; E. Horner. *c*, H. Draycott; F. J. Leach.

Any other Variety.—1, J. T. Lishman. 2, E. Horner. 3, W. C. Dawson, Otley. *hc*, W. Harvey. *c*, W. C. Dawson; J. Cundale, Ripon; H. Draycott; J. Thompson; H. Yardley.

Selling Class.—1, J. Hawley. 2, J. C. Ord. *vhc*, J. C. Ord. *hc*, J. Lister, Keighley; F. S. Clayton, Bradford. *c*, J. Lister; C. Anton, Petergate, York; J. Thompson; C. Cowburn; E. Kaye, Honley, Huddersfield; W. Harvey.

Rabbits.—*Yellow, White, and Tortoiseshell*.—1 and Medal for best Rabbit shown, B. Hudson, Hull. 2, A. H. Easton, Hull. *hc*, J. E. Crofts, Bawtry; A. H. Easton, Hull; F. Ashton, Drypool, Hull; T. Ingham, Belmont, Leeds; J. F. Stott. *Black and White*.—1, A. H. Easton. 2, A. Chapman, York. *Self-coloured*.—1, J. G. Quick, London. 2, C. Gravill, jun., Thorne. 3, T. Taylor, York. *hc*, E. Butterworth, Rochdale; A. H. Easton; J. G. Quick. *Grey and White*.—1, T. Ingham, Leeds. 2, J. Spenceley, York. *hc*, T. Taylor, Croppergate, York; W. Tomlinson, Barton-on-Humber. *c*, C. King, St. John's Wood. *Selling Class*.—1, T. Ingham. 2, C. King. *hc*, C. Gravill, jun.; C. King; J. G. Quick; W. Allison, Sheffield. *c*, W. Allison.

Judges.—Mr. Edward Hewitt, Birmingham, and Mr. Teebay, Preston, for *Poultry*; and Mr. Hutton, of Pudsey, for *Pigeons and Rabbits*.

MENHENIOT POULTRY SHOW.

(*From a Correspondent.*)

The second annual Show was held in a large tent on the 3rd inst., and with the exception of the Bath and West of England Shows held at Truro and Falmouth, was the largest and best ever held in Cornwall. Last year the entries were about ninety, and this year, owing to the publicity given it in your columns, the entries were upwards of 200, and the birds were of a very high class, especially the Game, of which there were seven classes out of the fifteen for fowls, including an extra class for Tassels, birds having a large crest or topknot of feathers on the head, whilst others of this class had a drooping tuft of feathers fully 3 inches long hanging gracefully down over the hackles. There was another extra class for *Hennies*—birds that were formerly bred for the cockpit, but are now nearly extinct except in the somewhat slow unchanging west. The first-prize pen proved the centre of attraction, as scores of visitors had never seen such birds, and the cock was so perfectly hen-feathered that many could not be induced to believe them to be other than two hens. The *Hamburghs* were a splendid lot, and all the classes were of average merit. The following is the prize list:—

Dorkings.—1, — Beard, St. Blazey. 2, J. H. Nicholls, Lostwithiel.

Cochins.—1 and 2, — Beard.

Brahmas.—1, J. Beard. 2, — Maddox, Launceston.

Game (Black Red).—1, — Higham, Morchard Bishop. 2, — Davey, Perranwell.

Game (Duckwing).—1, J. Toll, jun., Menheniot. 2, — Kendall, Liskeard.

Game (Brown Red).—1, E. Snell, Menheniot. 2, — Harris, Morsewater, Liskeard.

Game (Any variety).—1, — Stephens, Liskeard. 2, Withheld.

Game (Tassel).—1, — Taylor, Liskeard. 2, A. Barrett, Menheniot.

Game (Henny).—1, — Harris. 2, T. Warden.

Hamburghs (Golden-pencilled).—1, S. R. Harris, Cusgarne St. Day. 2, J. H. Nicholls.

Hamburgh (Silver-pencilled).—1, J. Roberts, Menheniot. 2, S. R. Harris, Cusgarne St. Day.

Hamburghs (Golden-spangled).—1, S. R. Harris. 2, Capt. Pryor, Menheniot.

Hamburghs (Silver-spangled).—1, J. Toll, jun. 2, S. R. Harris.

Polish.—1 and 2, J. Beard.

Any Variety.—1, S. R. Harris (Black Spanish). 2, — Polgreen, St. Germans (Minorca).

French.—1, J. Nicholls (Crêve-Cœnr). 2, W. May, Liskeard (Crêve-Cœur).

Single Game Cock.—1, S. R. Harris (Brown Red). 2, F. Richards (Black Red).

Single Cock (Any variety).—1, — Brewer (Black Spanish). 2, — Bennalick, St. Austle (Cochin).

Ducks (Aylesbury).—1 and 2, — Hawkin.

Ducks (Rouen).—1, J. Toll, jun. 2, — Loite, St. Austell.

Ducks (Any variety).—1, — Hicks, (Common). 2, R. Skin, Menheniot (Common).

Geese.—1, — Burrows, St. Cleer (White). 2, T. Pollard, Menheniot (White).

Turkeys.—1 and 2, W. C. Herring, Menheniot.

Bantams (Any variety).—1, Miss S. Rabey, Menheniot (White). 2, — Tucker, St. Germans (White).

Game Bantams.—1, — Hoskin, Plymouth (Black Red). 2, — Lovring, St. Austell (Black Red).

PIGEONS.

Carriers.—1, — Pryor, Redruth (Black). 2, — Snell, Menheniot (Black).

Tumblers (Almond).—1, — Chudleigh, Plymouth. 2, J. Skin.

Tumblers (Any variety).—1, R. Skin. 2, Miss Herring.

Jacobins.—1, — Deacon, Liskeard. 2, Miss Herring.

Runts.—1, J. Snell. 2, W. C. Herring.

Fantails.—1 and 2, — Pryor.

Any Variety.—1, — Pryor (Owls). 2, — Brewer (Dragoons).

Judge.—Mr. Leeworthy, St. John's Cottage, Newport, Barnstaple.

KILMARNOCK ORNITHOLOGICAL SHOW.

The eighteenth annual Exhibition of the Kilmarnock Ornithological Association was held November 27th, in the Corn Exchange Hall and Market. The entries numbered about 700, and the general quality of the specimens shown was excellent. In our next number we shall give further particulars. The following is the prize list:—

Spanish.—1 and 3, Miss A. Hodgarth, Paisley. 2 and Timepiece, J. Moodie, Paisley.

Dorkings (Any colour).—1, T. Briden. 2, T. Smellie, Moorfield, Kilmarnock. 3, A. Yeudall, Glaston. *hc*, T. Smellie; J. Robertson. *c*, J. Robertson.

Brahma Pootras or Cochin-Chinas.—1 and Timepiece, A. Geddes, Kilmarnock. 2 and *c*, A. Robertson, Kilmarnock. 3, G. Y. Dart, Dumfries. *hc*, W. Gibb, Motherwell.

Scotch Greys.—1, J. Fulton, Beith. 2 and *hc*, R. Blair, Johnstone. 3, J. Fleming, Beith.

Hamburghs (Gold-spangled).—1 and Timepiece, J. Jardine, Kilmarnock. 2, R. Mackie, Stewarton. 3, A. Watson, Troon. *hc*, H. Pickles, jun., Earby. *c*, W. A. Hyde, Ashton-under-Lyne; R. Watson, Kilmarnock.

Hamburghs (Gold-pencilled).—1 and Medal, W. Creelman, Kilmarnock. 2, R. Muir, Cairnhill. 3, J. Walker, Birstwith. *hc*, J. Richmond, Kilmarnock.

Hamburghs (Silver-spangled).—1 and Timepiece, D. Skeoch, Stewarton. 2, R. Bruce, Busby. 3, R. Mackie. *c*, G. Pitt, Ringford.

Hamburghs (Silver-pencilled).—1, H. Pickles, jun. 2, J. Walker. 3, D. Skeoch. *hc*, J. Gray, Airdrie. *c*, W. Gibb.

Polands (Topped).—1, H. Pickles, jun. 2 and 3, Countess of Eglintoun and Winton. *c*, R. M'Nab, Govan.

Game (Any colour).—1 and Timepiece, J. H. McNab, Barrhead. 2, J. Waddell, Dumfries. 3, R. Kerr, Thornhill.

Game Bantams (Any colour).—1 and Timepiece, Bellingham & Gill. 2, R. Watson. 3, A. Mackay, St. Quivox. *hc*, W. Walker, Kilbarchan.

Bantams (Black).—1 and Timepiece, J. Scoular, Kilmarnock. 2, S. and R. Ashton, Mottram. Extra 2, J. Jardine.

Bantams (Any other variety).—1, G. Young, Kilmaurs. 2, J. Gray. 3, R. Stirrat, Dalry.

Any other Distinct Breed.—1, A. Jamieson, Kilbirnie. 2, Miss H. Patrick, Beith. 3, J. Allan, Kilbirnie. *c*, R. Frew, Kirkcaldy; J. Blair, Kilmarnock.

Ducks (Aylesbury).—1 and 3, A. Robertson. 2, A. J. Mutter, Kilmarnock.

Ducks (Rouen).—1, 2, and 3, A. Robertson.

Ducks (Any other variety).—1, S. & R. Ashton. 2, J. Robertson. 3, J. Dickie, Gateshead.

Any Variety.—1 and 2, A. J. Mutter. 3, D. Skeoch.

PIGEONS.

Pouters (Any colour).—1, Timepiece, and 2, J. Miller, Glasgow. 3, J. Mitchell. *hc*, J. Sharp, Johnstone. *c*, J. Waddell, Dumfries. *Bred in*

1809.—1, J. Miller. 2, D. M'Naught Kilmaurs. 3, D. Munn, Kilmarnock. *hc*, H. Thomson, Glasgow. *c*, J. M'Crae, Kilmarnock.

Carriers (Any colour).—1, J. Muir, Glasgow. 2 and *c*, J. Kerr, Kilmarnock. *hc*, A. Brown. *c*, G. Y. Dart, Dumfries. *Bred in* 1869.—1, W. H. Mitchell, Birmingham. 2 and 3, G. White, Paisley. *hc*, A. Wardrop, Kilmarnock. *c*, F. Love, Kilmarnock.

Tumblers (Short-faced, any colour).—1, J. Fielding, Rochdale. 2, J. Muir, Kilmarnock. 3, J. Hawley, Bingley. *hc*, A. Sim, Kilmarnock. *c*, F. D. Wood, Edinburgh.

Tumblers (Common, any colour).—1, W. M'Kindlay, Kilmarnock. 2, R. Blair, Johnstone. 3, J. Hawley. *hc*, A. Mitchell, Saltcoate. *c*, W. P. Adam, Tour.

Fantails (Any colour).—1 and Timepiece, J. Sharp. 2, J. Galt, Kilbirnie. 3, R. Gibson, Gateshead. *vhc*, J. Kerr. *hc*, J. Muir. *c*, R. Blair.

Jacobins (Any colour).—1, R. Yardley, Birmingham. 2, J. Waddell. 3, J. Sharp. *hc*, J. Hawley. *c*, W. M'Kindlay.

Barbs (Any colour).—1, J. Fielding, jun., Rochdale. 2, H. Yardley. 3, J. Muir. *hc*, J. Sharp. *c*, J. Hawley.

Trumpeters (Any colour).—1, J. Hawley. 2, J. Sharp. 3, J. Muir. *hc*, A. Wardrop. *c*, A. Kitchie, Irvine.

Nuns (Any colour).—1, J. Murray, Darvel. 2, R. Scott, Galston. 3, T. Imrie, Ayr. *hc*, H. Yardley.

Common (Any colour).—1, W. Kerr, Dalry. 2, W. M'Kindlay. 3, J. Lamont, Kilwinning.

Any other Distinct Variety.—1, J. Fielding, jun. 2, J. Hawley. 3, J. Muir. *hc*, J. Sharp. *c*, H. Yardley.

Any Variety.—1, G. B. Phillips, Ayr. 2, J. G. Orr, Beith. 3, J. Wilson, Beith.

CANARIES.

Yellow.—*Cock.*—1, J. Crawford, Beith. 2, A. Kelly, Paisley. 3, J. Conn, Kilwinning. *Hens.*—1, J. Gray, Airdrie. 2, W. Reid, Kilmarnock. 3, A. Kelly.

Buff.—*Cock.*—1, R. Crawford, Kilbirnie. 2, J. Gibson, Paisley. 3, M. Howard, Overton. *Hens.*—1, A. Kelly. 2, J. Gray. 3, R. Watson, Kilmarnock.

Piebald (Yellow). — *Cock.*— 1, J. Noris, Ardrossan. 2, T. Christie, Glasgow. 3, J. W. Will, Errol. *Hens.*—1 and 2, A. Kelly. 3, J. Crawford.

Piebald (Buff).—*Cock.*—1, J. Fisher, Dalry. 2, J. Gray. 3, H. M'Kissock, Glasgow. *Hens.*—1, J. Wilson, Beith. 2, W. Hunter, Kilbirnie. 3, J. Wilson, Galston.

Goldfinch Mule (Yellow).—1, J. R. Adam. 2, G. Brydon, Ayr. 3, R. Brown, Newmilns.

Goldfinch Mule (Buff).—1, J. Gray. 2, W. Gondie, Ayr. 3, G. Brown, Kilmarnock.

Goldfinch.—1, T. Conn. 2, J. Fisher, Dalry. 3, J. Fergeson, Kilmarnock.

Canary (Clean).—1, A. Kelly.

Linnet Mule.—1, T. M'Murtrie, Riccarton Toll.

The Judges were: for *Poultry*, Messrs. J. Kidpeth, Edinburgh; J. Lindsay, Stewarton; J. Paton, Stewarton; and R. Calderwood, Kilmarnock. *Pigeons:* Mr. James Hnie, Glasgow; and Mr. William Brown, Wishaw. *Canaries:* Messrs. G. Masterton, Glasgow; T. Fernie, Paisley; R. Paterson, Howwood; and S. Brown, Glasgow.

BURTON-ON-TRENT BIRD SHOW.

This Exhibition of Cage Birds took place on the 20th of November. As a first Show it was, in every respect, a decided success, a result which must be mainly attributed to the exertions of an indefatigable Committee, who spared neither trouble nor expense in the management of the Show. The Exhibition was held in the Town Hall, and throughout the day was well patronised. Some splendid pens of *Game*, Silver-pencilled and Golden-spangled *Hamburghs*, Game *Bantams*. *Pigeons*, *Parrots*, and many specimens of *British Birds*, added much to the interest of the Exhibition. The prospect for the future Shows is most encouraging. The following are the awards:—

BIRDS HATCHED IN 1869.

Norwich (Clear Yellow).—1, J. Anthony. 2, W. Holmes. 3, R. Cowley. 4, W. Holmes.

Norwich (Clear Buff).—1, J. Anthony. 2 and 3, W. Holmes. 4, R. Cowley.

Norwich (Marked Yellow).—1, J. Anthony. 2, T. Newbold. 3, R. Cowley.

Norwich (Marked Buff).—1, J. Dent. 2, J. Anthony. 3, W. Holmes.

Norwich (Variegated Yellow).—1 and 2, R. Cowley. 3 and 4, J. Dent.

Norwich (Variegated Buff).—1, R. Cowley. 2, W. Holmes.

BIRDS OF ALL AGES.

Belgians (Clear Yellow).—2, R. Cowley.

Belgians (Clear Buff).—1, R. Cowley. 3, T. Newbold.

Belgians (Variegated Yellow).—1, W. Gretton.

Norwich (Clear Yellow).—1, W. Holmes. 2, T. Newbold.

Norwich (Marked Yellow).—1, R. Cowley. 2, W. Holmes.

Norwich (Marked Buff).—1, J. Anthony. 2, R. Cowley.

Norwich (Variegated Yellow).—1, J. Anthony. 2, T. Newbold.

Lizards (Golden-spangled).—1, J. Anthony. 2, W. Holmes.

Cinnamon Yellow.—1 and 2, W. Gretton.

Goldfinch Mules.—1, W. Holmes. 2, J. Dent. 3, W. Gretton.

Goldfinch Mules (Crested).—1, W. Holmes.

Bullfinches.—1, W. Holmes. 2, J. Chiswell.

Skylarks.—1, J. Chiswell. 2, J. Anthony.

Mr. G. J. Barnesby, of Derby, was the Judge.

BIRMINGHAM RABBIT AND CANARY SHOW.

The twenty-third annual Show of Rabbits and Canaries was opened on the 29th ult. in the Odd Fellows Hall, Upper Temple Street. About one hundred Canaries and forty-three Rabbits were entered. Mr. H. Attwood's tortoiseshell buck carried off the first prize for length of ears (22½ inches), and an extra prize, given by Mr. Collins, for the best particular colour, all properties. Mr. J. Curtis's black and white doe gained the second prize for length of ear (22¼ inches), and the first for weight, 12 lbs. Mr. Beech's black and white doe, Mr. Pratt's yellow and white buck, Mr. Hincks's tortoiseshell buck, and blue and white buck, Mr. Attwood's gray and white buck, and Mr. Curtis's grey doe, were the first-prize winners in the classes for all properties. Extra prizes for self-colour, and black and white were awarded to two Rabbits exhibited by Mr. Curtis.

Of *Canaries* the Belgian classes included some very fine specimens. Mr. J. Turner's birds won three first prizes in these classes, and Mr. G. Corbett, sen., in two classes. Mr. G. Smith obtained a first prize. There was a good display of Norwich Canaries, in which classes Mr. G. Corbett, jun., obtained four first prizes, Mr. J. Turner one, Mr. W. Smith one, and Mr. W. Corbett one. Two silver cups were presented, as extra prizes, to Mr. J. Turner for the best Yellow Belgian in the show, and for having obtained the greatest number of prizes in all classes. An extra prize, for the best variegated Yellow Belgian, went to Mr. G. Corbett, sen. Messrs. B. Guest, H. Hall, J. Newton, and B. Johnson were the Judges.

CANARIES.

On the 11th and 18th of November, I read in the Journal the report of Mr. W. Blakston, of Sunderland, on the Darlington and Stokesley Canary Shows, and I beg to make some remarks thereon.

Referring to the Darlington Show, I was very much astonished at his remarks on the Belgian Canary. It must be quite patent to the most casual observer in "the fancy," that Mr. Blakston is not an admirer of this very noble and elegant variety of Canary, and therefore I would observe that, if a man has no fancy for this particular variety of bird, he is certainly not a proper person to judge of its merits. His remarks in reference to the Green Canaries are very vague. It is a well-known fact that in the northern counties of England, especially among the pitmen, the clear Green Canary is a great favourite; but the ambition of these men is to bring them as nearly as possible to the pure-bred Belgian, in size, symmetry, and contour. The "pea-green," as Mr. Blakston very inaptly terms it, is a colour never seen in a Canary; they are generally very dingy in colour, and black-green, or blackish-green, would be a much more appropriate designation. The Norwich Greens were bred, originally, from the Lizard Canary; and by judicious pairing and crossing, the Clear Jonque and Mealy Norwich varieties have been established.

I will now pass on to the Stokesley Show. I would like Mr. Blakston to give a proper definition of the Yorkshire Fancy. I am informed on very creditable authority that this variety of bird is unknown in Sunderland. The Norwich Fancy, London Fancy, Yorkshire Fancy, Glasgow Don or Scotch Fancy, and many other varieties are all mongrels, so to speak, as the whole of these varieties have been obtained by judicious crossing from other kindred and distinct varieties. If a man wishes to improve the size and shape of his birds he naturally crosses with a Belgian; if colour is his object, then Norwich or London Fancy, or Lizard, particularly for marked birds.—R. C. Wallace, *Berwick.*

SPURIOUS HONEY—DRONES IN NOVEMBER.

Although I have no personal knowledge of the frauds that are perpetrated in the honey market, I have no doubt that Mr. Pettigrew has good grounds for the allegation he has made. Beautiful-looking combs can be manufactured from sugar, and when filled with syrup it is all but impossible, if judged merely by the eye, to detect their spurious character. As showing how parties may be deceived, I may mention what came under my own observation.

The summer of 1854 was cold and wet, so much so as to prevent any collections being made from the fields, and consequently all my hives had to be kept alive by sugar, which was liberally dispensed. By some awkward manipulations on my part, an accident happened to one of them, whereby several of the well-filled combs were broken down. When carried into the house they presented a very tempting appearance, and a lady and gentleman who happened to see them were very anxious to taste the new season's honey. I assured them that the combs that looked so attractive were merely filled with sugar and water; but my statement was received with incredulity, and I had to yield to their request and give them what they required. To my astonishment, on tasting the artificial material, they pronounced it excellent honey, and they proved that they relished it by the quantity they ate. Seeing how the eye could

be deceived, it was resolved to play a practical joke upon one of the members of the household, who was known to be exceedingly fond of honey. A piece of beautiful empty comb was selected, and the cells neatly filled with codliver oil. It was then placed in a situation where the lover of honey was sure to find it. The result was just as expected—the deception was not perceived until the nauseous preparation had been taken into the mouth, and you may be sure that the wry faces that followed occasioned immense merriment to those who were in the secret. Knowing these facts, I have often thought that it would be no very difficult matter for unprincipled apiarians to foist upon incompetent judges a spurious article.

Hitherto I have refused to allow myself to be nominated as a judge of honey where prizes are given; but if I should at any time be placed in that honourable capacity, I should certainly insist upon exercising the sense of taste before making an award. The prizes offered should be of sufficient value to compensate exhibitors for any disfigurement of their glasses or supers.

Whilst thus giving my opinion that sealed combs made entirely from sugar may be of such beauty as to deceive the eye of the most practised and competent judges, I must at the same time confess that I know nothing of the fraudulent practices that are said to prevail, having had no experience whatever either in buying or selling honey.

But I pass to another subject. In the interesting account which Mr. Lowe gave in 1866 of his experience of the Egyptian bee, mention is made of drones making their appearance at a very late period of the season in one of his colonies. I thought at the time that it was one of the peculiarities of Apis fasciata. His words are, "At this moment the Egyptian colony is without exception the most populous in my apiary. The maturing brood is still plentiful, young drones have again appeared. The appearance of drones at the end of October is a perfect anomaly with me. I have observed, however, that the young larvæ are now being dragged out." Drones in a healthy hive, with a perfect queen, so late as the end of October are certainly anomalous, but what will he think of drones in November? Passing round my apiary on November 8th, I saw them coming out in great numbers from one of my hives. I naturally concluded that the old queen had disappeared and given place to another, which had failed in meeting a husband, and had therefore become a drone-breeder. To satisfy myself I opened the hive on the following day and made an examination, but no change had taken place—my old queen with clipped wings, reared a year ago, was still present, active, and looking well. The hive was crowded with bees and a large proportion of drones, all the combs being well filled with honey. Yesterday (November 22nd) the drones were out for an airing, and what is very singular, no attempt has been made by the bees to expel them. Will Mr. Lowe favour us, if possible, with an explanation of the mystery?—R. S.

JOURNAL OF A LANCASHIRE APIARY.

I enclose a copy of this year's entries in my bee journal, and desire at the same time to tender my thanks to Mr. Pettigrew for his "minted syrup," to "B. & W." for his little book, and to "A Devonshire Bee-keeper" for his instructions "How to drive bees." I begged three condemned stocks, drove them, and joined the bees to my "keepers." The hive of my own, which I broke up (No. 1), I treated in the same way. Wasps have been a great nuisance this year, and have plundered a great weight of honey.—J. H. B., *The Fylde, Lancashire.*

No. 1, common hive, established June 18th, 1867. April 6th, 1869, weighed nett bees and honey, 37 lbs. June 28th, swarmed. Removed stock, and put swarm in old stock's place as soon as hived. Weighed the swarm at night, 7¾ lbs. The stock did not send out a second swarm. September, drove bees, and added them on Mr. Pettigrew's plan to another stock. Found 25 lbs. of honey in the hive, which I took.

No. 2, common straw hive, established June, 1867. 1869, April 6th, weighed 34 lbs. nett. June 29th, swarmed. Treated the swarm like No. 1. Weight of swarm at night, 6 lbs. There was no second swarm. September, added bees from a driven hive. October 9th, weighed 19 lbs. nett. October 11th, feeding gave three bottles.

No. 3, common straw hive, established June 18th, 1868. 1869, April 6th, weighed 27 lbs. nett. June 1st, commenced work in a small super. June 15th, commenced work in a nadir box hive. August 10th, took honey, 30 lbs. October 3rd, fed bees, and added a driven stock. October 22nd, not yet weighed.

No. 4, wood box hive, established June 18th, 1868. 1869, April 6th, weighed 23 lbs. nett. June 25th, swarmed; the treatment the same as for No. 1. Swarm weighed 7 lbs. 10 ozs. There was no second swarm. October 9th, weighed 31 lbs. nett.

No. 5, wood box hive, established July 1st and July 2nd, 1868, from two second swarms joined. 1869, April 5th, weighed 19 lbs. nett. June 25th, commenced work in super. August 12th, removed super containing 28 lbs. of the most beautiful honeycomb. October 9th, weighed 22 lbs. nett.

No. 7, square straw hive, established June 29th, 1869. September 1st, joined a driven stock. October 9th, weighed 13½ lbs. nett. October 11th, feeding commenced.

No. 8, square straw hive, established June 28th, 1869. September 2nd, joined a driven stock. October 9th, weighed 21½ lbs. nett.

No. 9, square straw hive, established June 25th, 1869. October 9th, weighed 27½ lbs. nett.

Results of Year.—No. 1, honey, 25 lbs.; swarms, one. No. 2, honey, none; swarms, one. No. 3, super honey, 30 lbs.; swarms, none. No. 4, honey, none; swarms, one. No. 5, super honey, 28 lbs.; swarms, none. Nos. 7, 8, and 9 are the three swarms of this year.

MODE OF INTRODUCING NEW QUEENS.

Your correspondent who on the 25th of November gave an interesting instance of queen encasements, may find in one of the recent numbers of "The American Bee Journal" a contribution from an able writer, in which he expresses the opinion that queens are sometimes "loved to death."

This leads me to remark that the latest German method of introducing new queens appears to be a very excellent one. The process is simple and speedy. Sprinkle the queen to be introduced, and the stock in which she is to be placed, with syrup strongly scented with grated nutmeg. Do this liberally, and allow a few minutes to elapse before disturbing the frames. Then find the queen to be removed, and place her, with a few of her subjects, in a cage, in case of accident. At once place the new queen upon one of the combs, and close the hive. Next day an examination should be made to see that all is right. I have made a very satisfactory trial of the plan, and think it has no equal.

This method possesses many advantages. The exchange is effected in one operation; no time is lost through the absence of the queen, even for an hour; and the bee-master who discovered it states that the result is certain.—A. L., *Reading.*

LIGURIANISING THE COMMON BLACK BEE.

About seven o'clock in the morning of the 28th of October I received a Ligurian queen and her attendants, but it was a morning most unsuitable for bee operations, as the ice was an inch in thickness; in short, it was a bitterly cold day. The bees after their long journey were very much chilled, indeed they appeared lifeless; but after being put into a warm room for a while they soon came to, and were very lively. Although it cost me a good deal of anxious thought, I am happy to state that her yellow majesty was introduced to her black subjects with perfect success. My difficulty was this—the stock to which I was about to introduce the queen was in a common straw hive, and I could see no chance of capturing the black queen, except by driving them, and to prevent loss of bees on such a day what was to be done? There is an old saying, "Want is no shift," or "Where there is a will there is a way;" so I decided to have the bees brought into my kitchen, where I succeeded in driving them into an empty hive; and in searching for the queen, which I captured in two minutes; only about three dozen bees flew to the window, all of which I returned without losing a single bee. This was about 3 P.M., and in an hour afterwards I found unmistakeable signs that the bees had discovered their loss. I then introduced the black queen to her old subjects, but first put her into a queen cage, where I left her until about eight o'clock next morning; then I took her out, and again left the bees queenless until I saw they had discovered their loss, which was about nine o'clock. I then introduced her yellow majesty in the same cage, and put her in the same place in the hive, and precisely at ten o'clock I opened the prison door; she was immediately well received by her new subjects, and I need hardly say that I feel very proud of my success.

I may here state that the queen cage is made of fine wire

cloth, 3¼ inches long, 1¼ broad, and half an inch wide, with a door on one end, having a wire attached to it, which on being pressed gently down, opens the door, and her majesty at once goes out, and is received gladly.

In conclusion, I may say that if the above mode of introducing queens is adopted and properly carried out, success will attend ninety-nine cases out of every hundred.—Benjamin Gregg, *Mauchline, Ayrshire.*

Two Italian queens, the first of their race which I have ever possessed, although always a bee-keeper, arrived all safe and right about seven o'clock at night. As it was a very hard frost when they came to hand, the next thing was to put them into their hives; and the weather being so frosty, I determined to put one of the queens in the same night. I therefore took No. 1 stock into a room, gave it a few puffs of tobacco, and closed the hive for a few minutes. The song of the bees told me when to commence searching for the queen, and on discovering I captured her, and put the Italian queen in a wire cage (a pipe cover), and fixed it on the comb, as described by Mr. Woodbury. She started to feed at once, and putting all the bees that had accompanied the queen into the hive, I closed it, and placed it again on its stand. Next morning all was peaceable and right.

Now for No. 2 stock. At noon next day I treated this in the same way, as it was still frosty, and put the queen in; but, to my disappointment, the bees worried every Italian that I put into the hive, so that there is not one left, and next day, on looking through the hive, it seemed all confusion, and on opening it I found that the queen cage was full of black bees, and the queen gone. I at once searched for, and on finding her, one of the black bees had her by one of her wings. I instantly killed the bee, and watched to see if I thought her safe or not, as the bees were running like wild things over one another. Two more set on her, but I killed them, and then caught her, and made her again a prisoner, as I saw she was not safe. I examined the comb that had the cage fixed on it to see how she had made her escape, and found that the bees had eaten down by the outside of the cage and up the inside to get to her, and that was the way she had escaped. I re-fixed her on a fresh part of the comb, and closed the hive again, and the bees continued so savage for four days that if I went near the hive they would dart at me from all directions. I opened the hive every day to see if the queen was still in the cage. On the fifth day they seemed more like settling. On the sixth day they were all clustered and settled, and on the seventh day I ventured to let the queen out, when they took to her, and she is now all right with her new subjects. In No. 1 hive I set the queen at liberty on the third day with every success, as I believe not one of her companions was killed.—M. A.

THE BACHELOR AND THE BEES.

A bachelor laird who resides in the *locale* of the Lomond Hills, in Fifeshire, having been presented with a jar of honey from a neighbouring cultivator of the soil and a bee-keeper to boot, became so attracted by the nectarious liquid that he resolved upon becoming an apiarian instanter. After considerable higgling he became possessed of a swarm of honey-gatherers and had them borne to his homestead this week, but owing to the severity of the frost, he, through a feeling of pity towards the insects, had them placed overnight in his bedroom and in front of a blazing big fire. The bee-master turned into bed to dream of flowery meads and ambrosial sweets, but towards midnight a drumming singing sound, as if a congregation of pigmies were at psalm-singing, aroused him from his repose. The entrance of the straw skep containing the colony had not been properly closed, and the swarm, thousands strong, were in activity around him! His loud cries for aid brought prompt assistance, but not without suffering keenly from the darts of the insects was he allowed to leave the room. Considerable difficulty was experienced in getting the bees returned to their former quarters, and the laird, having had enough of bee-keeping, has resolved never again to be so tempted by "sweets."—(*North British Daily Mail.*)

OUR LETTER BOX.

Game Fowls (*Hawkins*).—The book you mention is only reliable so far as the compiler obtained information from good authorities. We do not know what illustrations are used. There would not be a remunerative sale for the plate you wish for.

Books (*Australian Subscriber*).—There is no book with coloured or other plates devoted to Game fowls. If you enclose a post-office order for 13*s.*, with your address, and order the "Poultry-Keepers' Manual," and the "Poultry Portraits," you will have all we can help you to.

Crowing Pullet (*Henwife*).—There is a "sound unmusical" to poultry ears that approaches to a crow, but it is not one. It is not performed with "head and tail erect," but in a lack-a-daisical manner, with tail on the ground. It is about as much like a real crow as a sneeze is like a laugh. We never knew a hen crow when suffering from roup; the note produced is more like a long complaint. A crowing hen has an erect comb and a strutting air. We believe implicitly in the old saying—

> "A whistling girl, and a crowing hen,
> Are neither good for yards or men."

Buckwheat and Maize (*B. S. H.*).—Buckwheat is not good poultry food. Fowls will not eat it whole, and although it is used extensively in France for poultry purposes, it has not been found successful in England. The offal you mention is to be bought as "sweepings." It is handy stuff to throw down as feed, but in our opinion there is no economy in buying low-class food.

Ear-lobe of Silver-spangled Hamburghs (*Norice*).—The ear-lobe of a good Spangled Hamburgh cock must be white; any mixture of red is very damaging. Minorcas should have red and swarthy faces; this applies to all the breed. Silver-spangled Hamburghs do not improve as they get older, rather the reverse. The lobe of the cock should be white.

Plumage of Dark Brahma Pootra Cock (*Regular Subscriber, Ayr*).—It is common to have chestnut patches on the wing of a Brahma cock, but it should not, under any circumstances, amount to anything like a saddle. We do not think it is a cross, but we should not breed from him.

Hatching by Steam (*D. Wood*).—There is no separate work on the subject. There is a chapter and drawings of apparatus in the "Poultry-Keepers' Manual," which you can have at our office, price 7*s.* 6*d.*

Fattening Ducks (*F. C. S.*).—Your letter came too late to be answered in time to be useful to you. The best food for your Ducks would have been oats mixed with gravel, and at times oatmeal and bran. Many of the heaviest are made so by meat feeding. In our opinion the black streaks on the bill are unimportant; many of the best birds have it. A defective bill is one that is faulty-coloured throughout.

Food for Ducks (*J. S.*).—If your Aylesbury Ducks will not moult, it is probably because they lack condition and health. In such a case the body is fevered, and the skin by its heat dries up the pulpy stub of the feather. Ducks are not amenable to medicine, and the only treatment is by way of feeding. Give them oats, gravel, and bran, put in a shallow vessel, the bottom of which is covered with a sod of growing grass. They will eat that, and do well upon it, when they will eat nothing else. A good Duck and drake will weigh 12 lbs.

Sky Tumbler Pigeon.—"*Reader,*" after seeking long and in vain for this breed, inquires, "Where shall we turn our course of search for the Sky Tumbler Pigeon of pure English blood, untainted by Dove-house or the continental (Roller) strain admixture?"

Turkey's Head Swollen (*A. C.*).—We have known Turkeys attacked at all ages, but, as a rule, late-hatched birds are most subject to it. Your treatment was right; camphor pills would have been a good addition. They help to cure the disorder, and prevent it from being communicated.

Experimental Bee Hives.—"*An Experimental Bee-master*" writes to say that he wishes for "the appearance of some advertisements" of such hives. We can only say that we shall willingly insert them if sent to us.

Winter Management of Stewarton Hives (*Swanley*).—"Zinc, from its coldness, deleterious incrustations, besides draughts passing through the perforations, causes the bees much annoyance, as well as labour to stop up the perforations with propolis. It has, consequently, been long ago discarded from my apiary. Ten or a dozen years ago I was puzzled to ventilate a square hive whose sides were formed of glass all round. At last I hit upon the expedient of substituting, for the wooden slides between the moveable bars, strips of Cuba or India matting; and so thorough was the ventilation thereby afforded, even in the most severe frost, as recorded in "our Journal" at the time, that I forthwith condemned the wooden bungs and all other stoppers over the central apertures of my stock hives, and ever since have employed small squares of matting secured in their place with broad-headed small nails, and I find they answer the purpose admirably. My strongest Stewarton colonies, in the best situation and aspect of my apiary, are not interfered with, and do not suffer from dampness; but in the case of those in the more shady sheltered corners I invariably tack over the uppermost box an octagon piece of matting, and draw all the slides. Stocks here are placed in moveable wooden covers. Stewarton, like all other hives, must be protected by good warm outer coverings winter and summer. The invariable practice with Stewarton hives has been to remove the lower box or boxes, as the case may be, as soon as vacated by the bees, reintroduce the slides, wrap up the mouth with several pieces of paper to exclude dust and moths, and suspend in a perfectly dry loft or garret till the exigencies of the colony call for them the following season. Thus circumscribed, the bees get more readily out for their winter flights, breeding is promoted in the spring, and the lower boxes are freed from the falling debris and possibly excrements after long confinement. To keep the combs a little off the board I set my stocks on a shallow octagon eke 2 inches deep; fresh air circulates freely below, and facility is thereby afforded for feeding if required.—A Renfrewshire Bee-keeper."

Commencing Bee-keeping (*Amateur*).—All depends upon the object which you propose to yourself in commencing bee-keeping. If you mean to become a scientific apiarian you cannot do better than follow the example of "A Beginner," as detailed in page 354 of our present volume, and adopt the Woodbury frame hive. If, on the other hand, you intend only ordinary bee-keeping with the power of putting on an occasional super, Payne's improved cottage hive made somewhat larger than recommended in "Bee-Keeping for the Many"—say 16 inches in diameter, by 8 or 9 inches deep, will answer every purpose. Or you may, perhaps, find a *via media* in the Stewarton hive and mode of management. Spring is the best time for purchasing bees.

From observations taken near London during the last forty-two years, the average day temperature of the week is 44 5°; and its night temperature 33.1°. The greatest heat was 58°, on the 16th, 1849; and the lowest cold 7°, on the 16th, 1853; and 19th, 1859. The greatest fall of rain was 0.87 inch.

FRUIT-GROWING IN FRANCE AND ENGLAND.—No. 2.

IT is an idea very commonly entertained, that the French are much more "carpophagous" than ourselves. The favourite idea of a Frenchman used to be, and I fancy to some extent now is, a lean, skinny human being, who was for ever kicking about his spindly shanks in dancing, who never ate anything more substantial than a dish of frogs' legs, and who was contented with merely an Apple and a "*petit pain*," if in humble life; if wealthy, that he lived on "unconsidered trifles light as air," which were commonly called "kickshaws" (*quelques choses*). Such was the "Johnny Crapaud" of our forefathers; while the French ideal of an Englishman—an idea we helped to make permanent—was an obese bloated-cheeked creature, who never could relish anything short of a sirloin of beef, as underdone as possible, and of which something under 2 or 3 lbs. would alone suffice to appease his appetite, that to be washed down with quarts of "*palail*" or "*portère*." Such was, and, I believe, still is, to many Frenchmen, John Bull. Need I say how absurd all this is—that you may meet as many fat, pursy little men on the Boulevards as in Regent Street—and that the little fat man in the last "Punch," landed in a field, and apostrophising his steed as "Mister Timberjumper," gives by no means an incorrect notion of him? And as to fruit-eating, I confess I cannot see, that with all the immense facilities of the French, with a country stretching down to the far south, and even to sunny Italy (since the cession of Nice), they are greater fruit-eaters than ourselves. I am sure the Halles Centrales do not contain each morning anything like the supplies that Covent Garden does; the superior fruits, such as Pines, hothouse Grapes, and forced Peaches, are not to be seen; you can only see them in a few shops in the Palais Royal and the best parts of Paris. They have larger quantities of Melons and Figs, but then we beat them hollow in Gooseberries, Currants, and small fruit generally. You dine at a table d'hôte, what fruit do you see there? Generally a large dish of Calville Blanche Apple—a, to my mind, very much overrated fruit, and not for one moment to be compared with a Ribston Pippin or a Nonpareil; to this is added a dish of Duchesse d'Angoulême or Beurré Diel Pears. These are taken off, a few (in proportion to the number of guests) cut up, and about one-eighth of each considered as a fair quantity. Dine in a French house, and you will find the fruit at dessert bears no sort of proportion to the other accessories, while with us it is the main supply, other things being only accessory thereto. I have no means of ascertaining the relative proportions of fruit sent into London and Paris, but I am inclined to think, from what one sees, even taking into account the vast difference in size of the two cities, that there is a great deal more consumed in our metropolis than in Paris; for while in Covent Garden, in the early morning, you see it brought in in huge waggon loads, you rarely see at the Halles more than a light cart; in fact, I think the quantity much less. Fruit puddings and tarts, which form so usual an item in the fare of every family in this country, are unknown almost in France, and I am strongly of opinion that this idea of the French being so much more fruit-eaters and less flesh-eaters than ourselves, must be relegated to the same limbo of exploded notions as the idea that every Frenchman is a thread paper, and every second member of the community a dancing-master.

And now as to climate. As I have previously remarked in my notes on the vegetable culture of the two countries, there have been broached more wild and ultra notions on this important subject—important in its bearing on vegetable produce, but much more so in its bearing on fruit-ripening. Some have stated that there is no manner of difference, that the climate of Paris in no way differs from ours, and that if it did, it would be in our favour; that tho winters are colder, and the summers hotter and drier than our own; and that to make this an excuse for not having as good fruit as theirs, is merely the result of ignorance or laziness. On the other hand, there are those who tell you, "Oh! it is of no use talking of comparisons in fruit-growing. See what a splendid climate they have; what brilliant skies; how free from those nasty spring frosts that destroy our fond hopes of a fruit crop. Oh! of course, theirs is a most favourable climate for fruit-growing; no wonder that they have such fine productions." All wrong again; in fact, as in a great many cases, truth lies midway between these two extremes. There is a great similarity in the climate of Paris and London, but yet with all that there is a great difference also: the winters there are, no doubt, colder than ours, the frosts more severe, and the early spring frosts quite as treacherous; the Peach-growers of Montreuil can no more dispense with their "*paillassons*" than we can with our curtains and other protectors. The summers, too, are warmer, and it is in this that the great advantage consists. There is, as I have once before said, not more than 2° difference, but then it is a difference not of mere warmth, but of light and sun, and how much that avails in fruit-ripening we all know. There are just one or two simple facts that I would mention, as illustrating this fact. It is very rarely that the Grapes do not ripen in the open air in the neighbourhood of Paris, and that not merely on walls, but on trellises and espaliers. How often do our Grapes ripen even on walls? the Chasselas de Fontainebleau or Royal Muscadine being the kind most generally grown there, not nearly so hardy as many Grapes we see on cottage walls and outhouses in the south of England. Again, the large Cantaloup Melon ripens in immense quantities in the open air about Paris, not exactly grown there, for it is first grown in frames, and then the glasses removed, and the fruit grown and ripened without protection. It would hardly be possible to do this, I should fancy, in the neighbourhood of London. Now, I contend this gives a great advantage to the Peach-grower, but I am not so sure that is of much account in Pear and Apple culture. The same notions with regard to climate have prevailed concerning Jersey and Guernsey; but a writer long resident there has shown that this is a mistake also. My conclusions, then, on this much-vexed question

of climate, are these: that the Parisian growers have an advantage, but by no means a great one in this respect, and that it ought to tell in the superior quality of their fruit—whether it does so is another matter—and that were I growing for profit, I think I should, taking all things into consideration, be as ready to engage in the business in the neighbourhood of London as in Paris.

Having thus touched on these preliminary questions, I shall be ready now to enter on the subject of the cultivation of those fruits which especially claim our attention.—D., *Deal.*

FORCING PEACHES AND GRAPES IN POTS.

What a subject to approach—ripe Grapes and Peaches in April and May, by a self-taught amateur, and a mere dabbler in gardening; why, I can scarcely believe that I have done such things, but I have, and as the matter is so simple, and the operation incredibly easy, I must try and make it so in print. I must acknowledge to being a young gardener, for when between forty and fifty I rarely turned my attention to the art, and scarcely knew when to sow Peas or Onions. At seventy I am becoming an accomplished gardener, and by consulting my "Keane" once a-week all the summer, I know when to sow Lettuces and Leeks, and early and late Peas. I had a fine crop of Ringleaders the whole of last October, so that for the second time we were tired of green Peas.

To commence my subject in order, I must describe my forcing house. It is a lean-to, 70 feet long, and 10 feet wide, from 9 to 10 feet high at back, and from 4 to 5 feet in front. Its walls are of 9-inch brickwork; in the front wall there are sliding shutters, 3 feet by 1, placed 6 feet apart; in the back wall, quite at the top, and close to the upper ends of the lights, are sliding shutters of the same dimensions, and the same distance apart. These shutters, front and back, are quite necessary, as the lights are all fixed. They were formerly sliding sashes belonging to a lean-to greenhouse built by my father just seventy-two years ago, and the sash-bars are now like iron. Those old builders used rare timber.

Inside, a path 2½ feet wide is in the centre, and on each side is a raised bed, with 4-inch brickwork, the back one 3 feet high, that in front 2½ feet high. The latter is filled with earth up to the under surface of the 4-inch hot-water pipes, of which there are three resting on the mould. The border at the back of the house is also filled with earth, in which are planted diagonal cordon Peach trees trained to the back wall; in front of them, at intervals of 3 to 4 feet, are placed some low bush Peach trees in pots. On the hot-water pipes in front are placed Vines; these are shortened to 4 feet, and have eighteen fruiting buds on each. These Vines, like all here, have been trained close under the glass roofs of the houses, so that they are "short-jointed" and crowded with fruit buds. They will be allowed to bear from ten to twelve bunches each. Their treatment is as follows—they are placed on the pipes in the 11 and 12-inch pots they have grown in during the season, the soil is stirred to the depth of half an inch, and levelled so as to admit the water properly, and a slight dressing of chopped decomposed manure about half an inch in depth is placed on the surface. This is all the preparation required. As soon as the young shoots are some 6 inches long, the usual surface-dressing of horse droppings two-thirds, and of kiln dust one-third, saturated with liquid manure, will be given to 1 inch in depth. This will be repeated—say once a-month, till the fruit commences to swell, and then as more food is required, pieces of slate will be stuck in round the inside of the pot to support fresh surface-dressings. I may mention, that in default of kiln dust, one of the safest and best of stimulants, decomposed manure only, chopped, and saturated with liquid manure, may be used. I may here remark that I have so many inquiries made for kiln dust, so abundant in this malt-making village, that I have suggested to our chemist and druggist, Mr. Truswell, to have it ready in four-bushel bags for sale at a moderate rate. He will, I hope, advertise it in your columns.

This is now the fifth year of my Grape culture on 4-inch hot-water pipes, without any plunging material whatever, and with unvarying success. The pipes are generally at a temperature of 120° to 125°. The vigour given by this powerful dry heat is extraordinary. A Vine of the Madresfield Court Muscat in an 11-inch pot, with from 4 to 5 inches of surface-dressing, and standing on a single 4-inch pipe, made last summer four shoots of the aggregate length of 60 feet, stout, and full of fruit-buds. On examining the roots at the bottom of the pot in contact with the pipe, they were found to be large, succulent, and full of life; the fibres seem forced up by the heat or drawn up by the rich surface-dressing. I should mention that the shoots of this Vine, being required for propagation, were not shortened till each had attained the length of 15 feet.

Peach trees in pots for forcing are treated exactly as recommended for Vines, but they must not be placed on the hot-water pipes, but on the front border some 2 feet distant, and on the back border. In this inartificial house and by such simple treatment, I had last spring Early Beatrice and Early Louise Peaches ripe in May, closely followed by some other kinds. As I did not commence till January, and have this season commenced forcing December 5th, I hope to have them earlier, and the same with Grapes.

I have described accurately my house and my doings, and now suggest some improvement in the building of an early forcing house. It may with advantage be 12 feet wide, with four 4-inch pipes resting on the front border, and by making the border at back 3 feet wide only, two or more pipes may be placed against the wall supporting this border at the back of the house, not flatwise as in the front border, but in the usual way; they would not then interfere with the trees trained against the back wall. A house 12 feet wide could thus be arranged:—Front border 6 feet wide, path 3 feet wide, and border at back 3 feet wide. This would give room for many articles to be forced, particularly Roses and Strawberries. The latter I now place in front of my Peach trees on the back border, and have two or three crops during the spring. The treatment of forced Vines and Peaches as to syringing, &c., is so often given in your columns, that I need not mention it here.

I have but little to add, but that little may be of use to some of your readers. My house is heated by a 24-inch Arnott stove boiler, its cost 45*s.*, set inside, with a feeding cistern over it. Its setting is very simple, and after the manner of a washing-copper. The Vines are placed from 3 to 4 feet apart, and as they are only 4 feet high, and will be pinched-in closely, they will not shade the Peach trees injuriously. The bush Peach trees are from 2½ to 3 feet apart; the diagonal Peach trees on the back wall are 2 feet apart. An 18-inch Arnott stove boiler, costing 35*s.*, would heat a house 25 or 30 feet by 12, and what an amount of interest and luxury in forced fruit could be gained from such a house!

When a youth I looked upon the gardener who produced ripe Peaches and Grapes in May as a sort of demi-god, so mysterious seemed the science of forcing; now I am old I am surprised at its simplicity.

There are a few rules to be observed worthy of a thought, and even worthy of recapitulation.

1. Peaches and Vines to be forced should not be repotted. I have known them to bear fruit in spite of their roots being disturbed, but they are better left alone. The additional food wanted by the tree I prefer to give on the surface.

2. While Peach trees are in bloom abundance of air should be admitted, a little even by night. The Vines do not require this, but they do not mind it.

3. The Vines on the hot-water pipes will require abundance of water, which will run through the mould like a sieve. It is good practice to make the surface quite firm with a blunt stick, using it as a rammer.

4. Peaches will not require so great an abundance of water, but it is well, say in March and April, to make the surface-dressing firm.

5. A lean-to house may be economically employed to force Vines and Peach trees in pots without placing the former on hot-water pipes. A house 12 feet wide, heated by three 4-inch pipes in front, and three at back, placed over each other in the usual way, would do very well.

6. The boilers I have mentioned are made by Mr. Hughes, Bishop's Stortford. They are the best and cheapest of boilers for small houses. Their sizes are 14, 16, 18, 24, and 28 inches. The former will do for a very small house.

And now for my apology. I should not have troubled you with this had I not been much importuned by friends to give them some safe directions how to force Vines and Peaches, and so if you kindly admit this I shall be much relieved, for I shall refer inquirers to your columns.—Thos. Rivers, *Bonks Hill, Sawbridgeworth.*

Oxalis tropæoloides.—I have grown this for years; it is perfectly hardy. At first I kept a large supply of cuttings, and still keep a few for early planting; but I never fail, in spring,

to find an abundant crop of self-sown strong plants. The situation is in the north-east of Scotland, 700 feet above the sea level.—H. C. T.

AMONG THE ROSES.

Every rosarian looks with much interest for details of experiences with Roses during the blooming season; it is by the summing-up of these results that plans can be arranged for the future, certain sorts be selected for cultivation, and some be rejected; and so the cultivator passes onwards to another season's work, having, in addition to his own sum of results, the experiences of others by which to plan, purpose, and accomplish.

It may be asked, What have we in the way of good autumnal-blooming Roses? for what can be more agreeable to the rosarian than to be able to cut good blooms even up to that time when

"The rime lies on the Cedar boughs, the hoar frost on the eaves?"

We can appreciate them at that season more calmly than when our eyes were dazzled by their overpowering splendour, our attention distracted by their infinite number, and we cling to them fondly because so soon to leave us.

Looking through Mr. William Paul's nurseries at Waltham Cross about the end of September, I was enabled to note the following as fine autumnal bloomers among the Hybrid Perpetuals—viz., Alfred Colomb, bright fiery red; Alfred de Rougemont, a fine dark flower, which might be described as bright deep crimson shaded with purple; La Duchesse de Morny, a beautiful and delicate shade of rose colour; La France, a fine autumnal Rose, producing splendid blooms; Le Rhone, a very fine late variety, and a rich hue of colour; Lord Macaulay, bright deep crimson, very good; Madame Alfred de Rougemont, a capital white Rose, blooming in large clusters; Madame Victor Verdier, a Rose of which, Mr. W. Paul observed, too much cannot be said in praise, colour rich bright crimson; Madame Elise Vilmorin, scarlet crimson, large and very fine in the autumn, but of imperfect shape; Prince Camille de Rohan, dark crimson maroon, distinct in colour and very free of bloom; Souvenir de Dr. Jamin, very dark, of a deep bluish violet hue, distinct and fine; Souvenir de William Wood, dark shaded maroon, a fine autumnal-blooming variety, but apt to burn in the summer, and should not be included in a list of summer Roses; Turenne, a very pretty and pleasing hue of rosy red; and Victor Verdier, rosy carmine, but which comes much deeper in colour in the autumn.

Of the group of Bourbon Perpetuals two were especially worthy of notice—viz., Madame Gustave Bonnet, a very fine and beautiful flower that comes deep flesh-coloured when it first expands, but changes to pure white as the blooms reach maturity, and so profuse of bloom that the plants appear covered with buds and flowers; and Michel Bonnet, rosy peach, also very free of bloom.

One great lesson taught at Waltham Cross was, that there is nothing like the Tea Roses for autumn work, and they were very beautiful, old Gloire de Dijon yielding magnificent blossoms, as if defiant of the oncoming of winter with its frosted brow and sure destruction; but as all Tea Roses produce light flowers, there is much need of the showier and darker hues of the Hybrid Perpetuals to give them life and pleasant contrasts. As a bedding Rose Mr. W. Paul strongly recommends Souvenir de Malmaison, both as a free and continuous bloomer, and as being as fine late as it is early in the season.

Of the new Roses of 1868-69 the following small but interesting group should be noted by cultivators:—Leopold II., clear rose, slightly tinged with salmon, of fine form, large and full, and of vigorous growth; Madame Creyton, one of the very best of the new Roses of this date, the flowers having a deep rose centre and an edging of rosy lilac; flowers large, smooth, and very fine, and a somewhat late-blooming variety; Monsieur Journeaux, a fine deep reddish crimson flower, flowers of good form, plant of vigorous growth; Marquise de Gibot, pale bright rose, flowers globular and of good substance, and a constant bloomer; Marquise de Mortemart, alabaster white, tinted with delicate flesh in the centre, flowers large, growth vigorous, said to have been raised from Jules Margottin; and Perfection de Lyon, rose, the reverse of the petals silvery lilac, full, good shape, and to be depended on. Of the 1867-68 batch, Impératrice Charlotte, beautiful, pale rose, clear and delicate, flowers large, full, and freely produced, and of abundant growth, was one of the very best. All these belong to the Hybrid Perpetual division.

No one could, or at least should, think of going to Waltham Cross without inspecting the house of Tea and Noisette Roses ere he leave. That house is always a charming sight when the plants are covered with those exquisite fragrant flowers of so many tints of yellow. Scarcely ever without flowers, there are yet certain occasions when some kinds stand out distinctly from their neighbours because of their superb beauty of development. On this occasion I saw Solfaterre, very fine; Souvenir d'un Ami, also; President, carrying some fine flowers; Cloth of Gold, still in bloom, but not so grandly as it comes during the summer months proper—a variety, however, that must not be depended on for autumnal work; Belle de Bourdeaux, a rose-coloured variety that makes an excellent climber; Marquise de Foucault, a nice-looking Rose in a house, but the flowers are not quite double, and hang their heads so that they cannot be seen to the best advantage; Jaune d'Or, buff centre, the outside petals flushed with rose; and Climbing Devoniensis, respecting which Mr. Paul says that it blooms most profusely after it has been two years budded on the Dog Rose.

And now that the chill evenings have come, and curtains are drawn, and bright fires glow, who is so happy as the Rose-grower with the new catalogues before him? And it may be added in full truth, especially at that season of the year when festive occasions recur, and the wreaths of crimson-berried Holly garland the head of Christmas.

"What reeks it then that Nature's face is wreathed in crown of snow,
Or that the crimson Rose of June within her grave lies low?
Are there not springing in our hearts perennial flowers still,
Glad evergreens, bright evergreens, of friendship and good will?"

—Via.

HINTS TO COTTAGE GARDENERS.

In giving some advice to cottagers on the cultivation of a few vegetables for exhibition and other purposes, I shall confine myself to a limited number, commencing with the Onion.

It is well known that in some kinds of ground you may grow Onions to great perfection with little trouble, whilst in other situations it is almost impossible to grow them, or stay the sad havoc made by grubs in the early part of the season. An experienced gardener once told me it was a great advantage to sow early, and in this I quite agree. All Onion beds ought to be manured in the autumn, and sown, after being well trodden, in February, if the weather will permit. For preventing the attacks of the grub many things are advised; the most simple is a good dressing of soot, which is generally advantageous, but the grub that attacked the Onions during the drought of 1868 never flinched under soot-dressings in any quantity, and this season, having had the misfortune to sow on new land, which ought never to be done, the grub has been very destructive. A remedy which I have tried and can recommend is to boil an armful of Tansy, and water the bed with the liquor. I applied to one-half of a trial bed of six varieties another valuable mixture; this consists of soft soap and sulphur, a good handful of each, and two or three handfuls of soot, the whole mixed in a good-sized watering pan. The half of the bed to which this mixture was applied gave a fair average crop, while the Onions in the other half went entirely off.

In choosing the kinds worth growing, it cannot be too strongly impressed on the grower that inferior sorts occupy the same extent of ground. Nuneham Park is a first-class Onion, and has won with one exception wherever I have known it exhibited. The exception was when a gardener, who has grown it largely, set up six of the finest I had ever seen at an exhibition; there were thirteen competitors, and, to my surprise, he only took the second prize, the first being awarded to Bedfordshire Champion, sown, I was informed by the exhibitor, in the first week in February, and there was no dispute that the latter well merited the honour, and from having seen it grown elsewhere I have no doubt it is a great acquisition.

Peas.—For cottagers' use I would entirely discard the earliest varieties. Maclean's Advancer is a fine second early that I would recommend, and, being of a branching habit, it need not be sown so thickly as many cheaper varieties. Wonderful well deserves its name; it is one of the very best of croppers. Princess Royal is a cheap and useful sort, and should you fancy one of the tall sorts, Ne Plus Ultra is a fine Pea for exhibition purposes. Commend me to Veitch's Perfection for flavour; I almost fancy it stands in the first position. Do not sow it as usual, but plant the Peas like Beans, not less than 3 inches apart. Take off all damaged pods, and cut one off all double straps, and you will be surprised at the size and quantity of Peas you will obtain. Sow fifteen or sixteen weeks

before the crop is wanted, but it is better to sow twice. There are, no doubt, many other good Peas, but those named will give general satisfaction.

It does not seem to be generally known by cottagers in this northern part how prolific and what a fine dish Dwarf Kidney and Runner Beans are, otherwise they would be more generally grown.

Red Cabbage.—I think I may safely state we have in this neighbourhood the finest variety to be found in any part of the kingdom. It was raised by Mr. George Stockly, of South Hill, Chester-le-Street. It is well worthy of the attention of growers, as there can be no doubt about its quality, and it grows close to the ground. It may seem incredible, but heads have been grown to 42 lbs. weight. He intends to sell the small quantity of seed he has in stock in packets at 1*s.* each. Give the plants plenty of manure and sewage. If you have a good sort they are easily grown; if not, save yourself the trouble of trying. Should the grub attack the roots, apply the sulphur mixture as advised for Onions, and the plants will root afresh surprisingly.

Celery needs few words from me, as readers of your Journal are receiving plenty of information on the subject. Plants raised early in heat ought to be well protected from cold winds, or they are apt to become stunted, and are almost sure to bolt. You can scarcely give too much water. Use plenty of salt, and you will greatly improve both crispness and flavour.

Leeks, raised in heat, must be protected like Celery; give them plenty of sewage manure, for the ground can hardly be too rich. Plants from seed sown in the bed will occasionally prove better than those raised in heat, are not so apt to bolt, and for late use I prefer them.

Potatoes.—The favourites in this district are Lapstone Kidney, Gipsy Queen, round white, and the Gosforth Seedling, red.

Carrots and Beet.—Trench in the manure a good depth in the autumn. There is little fear but the roots will find it, and doing so to a great extent prevents their forking.

If not occupying too much of your space, I would like to urge the claim of small birds. A strong sympathy prompts me to advocate their cause, and in doing so I will not bring to the front those tribes that are the acknowledged friends of the gardener, but rather try to prove that the linnets and blackbirds are not our enemies but friends. It is annoying, I admit, to have our seed beds plundered by the white and green linnets; but, observe, those hard-billed plunderers subsist all the year round on small seeds, and but for these it would be simply impossible for our farmers to suppress the weeds or secure a crop. We all know the crow loves to abstract a Potato now and then, or treat his palate to a few grains of Wheat early in spring; still, he lives five months of the year entirely upon grubs, and I think handsomely repays his occasional depredations. The sparrow assists in disbudding our bushes, and is not so intent on the destruction of grubs as we should like to see him, but if equally divided his depredations are not so great after all; but where gardens and farm buildings are contiguous, I am afraid I must fall back on his diligence in acting the part of scavenger, which saves us from swarms of flies. I had that best of friends, a mother; she used to say she loved the sparrow, for he always sung "cheer up." The blackbird seems never so happy as when perched upon a tree of ripe Cherries; he feeds all the rest of the year upon grubs, excepting during the deep snows of winter, when a kind Providence supplies an abundance of haws and other wild fruit. Though in hard weather it may occasionally disbud his Plum trees, does it not delight the gardener to see the little bluecap sit so intently examining every branch, peering into every hole, with a seeming determination that nothing shall be left undone on his part to protect them from the ravages of the grubs which would emerge in spring?—Joseph Witherspoon, *Chester-le-Street.*

OPEN-AIR GRAPES.

We had again to thank the Rev. George Kemp for being the means of causing a very interesting display of Grapes grown in the open air to be made at a recent meeting of the Fruit Committee of the Royal Horticultural Society, at South Kensington, Mr. Kemp having on that occasion offered "prizes of £3 and £2 for the best six bunches of Grapes, grown in the open air without any protection whatever." We have to thank Mr. Kemp for his disinterested generosity in this matter, for his laudable endeavours to improve our out-door Grape culture. His is an example worthy of all commendation. We can only wish that by his kindly encouragement a little more attention may be paid to this much-neglected branch of gardening.

The exhibition of October 19th was in all respects a creditable one, if in point of numbers it did not equal that of last year. The fruit was in many instances superior, and this, too in a season not by any means favourable for Grape culture; last year, on the contrary, being one of the most favourable ever known. In 1868 the first prize was awarded to Royal Muscadine, the second to Black Hamburgh; in 1869 both the first and second prizes went to the Royal Muscadine Grape, thus again stamping it as the variety best suited to our climate, and most worthy of cultivation. The Grapes which obtained the first prize, exhibited by Mr. Miller, gardener to J. F. Friend, Esq., Northdown, Margate, were especially fine, the berries as large as well-grown hothouse fruit, and of most excellent flavour, with a little of that beautiful rosy tint so valued by the French. For comparison with our English fruits, Mr. Spinks (lately one of the students at Chiswick), jardinier-en-chef at the Château de Chantilly, near Paris, sent some examples of his own growth of the Chasselas de Fontainebleau (our Royal Muscadine), the Grape which Frenchmen prize above all others. These, although stated to be somewhat superior to the fruit ordinarily to be met with in Paris, suffered by comparison with the English productions of Mr. Miller. They bore somewhat more of the russety hue, and were, perhaps, a trifle riper. Mr. Miller's examples were, however, far larger in both bunch and berry, and nearly equal in flavour, as were also those from several other exhibitors. This contribution of Mr. Spinks proved extremely interesting, showing by direct comparison the difference between the fruits of the two countries. It was there shown that by a little extra care and attention in favourable localities, in ordinary seasons, we can in the open air of our own country produce Grapes nearly equal to the best of those at Paris. We are so prone to vilify our climate, and praise up the sunny skies of France, that unless facts to the contrary are laid before us we refuse doggedly to believe it, and thus fail to make the most of our own material.

It is worthy of remark that in the warm season of 1868 a great many varieties of Grapes were exhibited besides the Royal Muscadine—viz., Black Hamburgh, Black Prince, Espiran, Burgundy, Frontignans, &c.; whilst in the colder season of 1869 all of the exhibitions, excepting one Black Prince, which was very unripe, consisted of Royal Muscadine. The Black Hamburgh, Black Prince, &c., have not ripened well in the open air this season, yet the Royal Muscadines exhibited were fully better this year than they were last, thus affording another proof that it is the main variety to be depended on. It is also an excellent wine-making sort, as evidenced by the first-class certificate awarded to Mr. Fenn for his Royal Muscadine wine, in preference to that made from the Espiran and the Muscat of Alexandria.

I may here announce that Mr. Kemp intends still further to encourage the open-air cultivation of the Vine by again offering similar prizes, to be contested for next year at the last October meeting of the Fruit Committee; Mr. Kemp's desire in offering these prizes being to encourage amongst the humbler classes of the community a love for the cultivation of their own Grape Vines, so that the labourer in his cottage, with his family, may be able to enjoy their dish of Grapes grown around their own doors as well as my lord from his extensive vineries. Such good deeds, so quietly done, merit their own reward. They tempt us to hazard a wish for many more Rev. George Kemps.—Archambaud.

THE NEW ROSES.

I have for some time given up the notion of attempting to convey any idea of the Roses which are being brought out year after year across the Channel. I have been so often disappointed, seen flowers of which I had hoped so much turn out worthless—seen, also, flowers of which no one had ever heard anything take a foremost place, that one gives up in despair forming any estimate. Of late years I took as a safer guide the names of the raisers, and from their doings in past years argued as to the present. But even this was deceptive; and now the lists come over to us without the names of the raisers, so that even this opportunity is denied us. Even if one goes over to France the attempt is almost hopeless; the Roses at Lyons, where a considerable number of the new varieties are raised, are fully ten days or a fortnight earlier than those about

Paris, so that anyone would have to spend a considerable time in attempting to see them all; and then, even if there at the time, the bushes are so cut about for stock, if the kind be really valuable, that the flowers are either very scarce or give a very inadequate idea of their true character. As to relying on the character given by the raisers, why, they are all charming, magnificent, splendid, perfection, &c.

I was not in Paris this year until August, and consequently could not see any of the Roses, although the season was a very late one, and heard but very little; but there were two of which I heard a good deal, and when others than the raisers praise flowers—alas! such is human nature—we may be inclined to believe that there is something in them. One of these was *Louis Van Houtte*, raised by Lacharme, the raiser of Charles Lefebvre, and in which, if the description be anything like it, we may expect a worthy rival to that noble flower. The other was *Unique*, a Tea Rose, raised by Guillot fils, who has already given to us Madame Margottin, Adrienne Christophle, and Marie Sisley, and which is described by the raiser as of an entirely new character. There are already before me lists of between fifty and sixty Hybrid Perpetuals, about a dozen Teas, two Noisettes, three Bourbons, and a few in other classes. Now who is to decide as to which are the prizes and which the blanks in this long list? I for one cannot. We all know the prizes will be few. We are promised of white Roses, Blanche de Mera, Elise Boëlle, Madame Liabaud, Perle Blanche, Reine des Beautés, and Reine des Blanches, but whether they are better than Virginal, Mdlle. Bonnaire, Baronne de Maynard, &c., is doubtful. Then the rose, cerise, satin-like rose, &c., are in numbers. It would almost seem as if the French growers could adapt themselves to our wants. At one time we were all for crimson and dark Roses; but at last the cry was, "Hold! Enough! We want light-coloured and white flowers." And lo! as if by an enchanter's wand they flock in upon us, nor can we say without giving us something of real merit. Monsieur Noman and Baronne de Rothschild are sufficient to show us that. We must look forward, then, in hope. It is our good friends the nurserymen we must pity. What a perplexity they must be in! They cannot possibly order all. Which shall they leave out?—which propagate most of?—must be anxious questions, and I believe private information, or even personal survey, will help them very little. Happy they who are not thus tortured, and calmly wait their verdict.—D., *Deal*.

WINTER BEDDING PLANTS.

(*Continued from page* 432.)

It must not be inferred because common and easily-grown herbaceous plants are recommended that shrubs are objected to; on the contrary, where shrubs can be obtained for winter bedding there is no question that they add materially to the general effect. As I have expressed an unfavourable opinion as to keeping plants in pots for winter on account of the attention they require at a time when other things want looking after, I will here restrict the list of plants suitable to such only as transplant well; for, be it observed, they have to undergo that operation twice a-year. The better class of ornamental Hollies will not endure this treatment, and some of the Cypresses are equally bad transplanters; on the other hand, the common Aucuba will bear removal any month in the year, and the other plants here mentioned are also very accommodating in this respect.

Box.—Plants of different sizes are very useful, the tree Box being much prettier than the edging or the intermediate variety; the gold-leaved variety, so called, is not half so good as the plain green, having only a sickly look at a short distance off. A partially-shaded place during the summer is best, but not too much so, otherwise the shoots become too tender to bear the cold blasts after planting-out in October or November.

Irish Yew.—A few plants of this are often useful as centre plants for circular beds. In general it transplants very well, the thickly-matted roots retaining a ball of earth of sufficient size to keep the plant in good health all the winter, and in spring it can be taken back to its place with very little loss. In some cases, however, it may be advisable not to remove it again for eighteen months, missing one year.

Arbor-vitæ.—Like the preceding, this removes very well, and being faster-growing and more easily propagated, plants can be had for the ordinary filling-in of beds, and where variety is wanted they answer very well; but I am not very partial to it, as the plants are not of so lively a green as Box and some other shrubs, but they transplant well.

Laurustinus.—It need hardly be said this plant does not like to be twice removed in one season, but it will bear the ordeal once very well, and young plants loaded with flowers look well in a mild winter like last one, when even Camellias were in excellent bloom out of doors in December and January; but in exposed situations it is not desirable.

Santolina incana (Lavender Cotton).—This plant is not so much used as it deserves to be; its silvery foliage fits it especially for winter, but around shrubs we have permanent edgings of it which are much admired; they are cut-in rather severely in August, and make fresh foliage, and look well all winter. For plants intended for the winter garden a number of cuttings put in, say, about September, root during the winter and early in spring, when they may be planted out in some poor piece of ground well exposed to the sun, and by autumn they form neat stocky plants. This plant is one of my favourites for the winter garden.

Retinospora ericoides.—The beautiful violet tint which this plant assumes in autumn and winter entitles it to more notice than it often receives, and the impression that it only thrives in a peaty soil is certainly an erroneous one, for here it does well in a soil exactly the reverse; and having a number of plants of it not all wanted for permanent positions, I have for several winters had some taken up in autumn for the winter beds, and with a successful result; at the same time I cannot say they have all done so well when removed again in March.

Stachys lanata.—"A summer plant," some will say, but it is, nevertheless, a winter one also, and does good service with very little trouble. In most places some plants of this will be found in the shrubbery or some out-of-the-way spot; these being pulled to pieces not too small, each with sufficient root at the layer-like stalk end, may be planted in separate patches, and they look tolerably well, but certainly not so well as the variegated Arabis mentioned in my previous article, but being a plant easily obtained it may be tried with advantage.

Saxifraga hypnoides.—I am not sure that this plant is so well adapted for winter as for a permanent position on some shady rockwork, but in an emergency it may be tried. It is a low mossy-looking plant, of an intense green, and looks well in winter.

Saxifraga rotundifolia.—I am not exactly sure whether I have given the true botanical name to this plant, but it can never be confounded with the first-named species, as this has foliage as large as that of a full-grown Beet, but of a bright green hue. Its flowers are pink, forming a large spike sometimes a foot long. Occasionally I have used this plant, but severe weather injures it very much, and I would hardly advise its use excepting where variety is wanted.

Sedge.—Yes, the common Sedge of the ditches, which, with the exception of Helleborus fœtidus and Arabis albida variegata first mentioned, I believe we patronise more extensively than any other plant, and at a little distance it is easily mistaken for Tritoma, or something of that kind. As a plant it may be said to cost nothing; nevertheless a little attention is due to it, and in the summer, say about the beginning of August, it is well to look round the ditches to which cattle have not access, and cut off the the tops of a number of plants; the after-growth will be shorter-leaved, and more suited to the purpose. The fine spreading habit of this plant well suits it for winter bedding, while in the sun its foliage shines beautifully. I need hardly say it transplants well, and until the dry winds of March set in its foliage seems unimpaired, provided bushy short-leaved plants have been selected. The longer-leaved ones are equally hardy, and look as well at first, but heavy showers break them down. The common Sedge is one of the most useful plants I know for winter decoration, and I have used it for many years.

Sedum glaucum.—This small, low-growing, compact little plant can only be used to advantage as an edging, or in very small beds, where it may be worked into any fanciful figure that may be desired. It is quite hardy, and any overgrown edging (and this plant spreads very fast), may be appropriated for the purpose with advantage. Its pale grey hue is on the whole pleasing.

Iris.—A variegated variety of the evergreen class can be worked in very advantageously where the situation is suitable; but it is not so hardy as some of the plants named above, still I have in past years had recourse to this plant.

Golden Feather Pyrethrum.—My experience with this only dates back to last winter, in which it survived and looked well, but it wants going over from time to time, as it pre-

sents a certain amount of dead foliage which requires clearing off; in mild weather, however, it looks well, and as it is easily obtained from seeds, and probably the plants doing duty in summer may also be made to do so in winter, as in my case, there will be difficulty in obtaining sufficient plants for all purposes. It seems to bear transplanting very well, and with me is quite hardy.

AUCUBA JAPONICA.—It is only necessary to say that this is one of the very best shrubs I know for winter bedding, transplanting readily, and looking well the whole of the winter. It propagates easily from cuttings put in during October.

AUBRIETIA PURPUREA VARIEGATA.—This pretty-growing plant seems well adapted for winter decoration, and answers that purpose well, but I have not had sufficient experience of it in quantity to speak of its effect in the distance; for close inspection I know of nothing more effective.

STIPA GLAUCA.—This grey-coloured Grass is effective, being of stiff and upright growth, and so is a kindred species FESTUCA GLAUCA. Both are adapted for winter. I am sorry I cannot speak so well of Dactylis glomerata variegata, which somehow has never done well here.

ARTEMISIA ARGENTEA.—I cannot recommend this plant until I have had further trial of it; its foliage is all that can be desired, but it seems not to be so hardy as desirable.

ALYSSUM SAXATILE VARIEGATUM.—This is a handsome plant, both in flower and not; but like most variegated plants it does not flower so freely as the plain-leaved, but is on that account the better for winter use; as the time it has to be removed being about the time of its flowering, some reluctance might be felt at transplanting it when just coming into beauty.

VARIEGATED THYME.—A pretty plant that may perhaps be worked in to advantage, but I have not used it.

VINCA ELEGANTISSIMA.—I have not used this for winter decoration for many years, in consequence of its being a prominent feature near the spot where winter plants are wanted, but it answers well.

PINKS.—Bushy plants of these look well where they can be had, their appearance in winter being good, and if only grown for that season, seedlings of some common kind might, perhaps, be quickest grown. I generally use the plain white, which strikes more freely and grows faster than better varieties.

Amongst other shrubs which we have at times pressed into winter service, Cupressus Lawsoniana has answered more than once admirably; the Red Virginian Cedar not so well, but I have not had so much experience with it. The common Laurel has also occasionally been used, and in favourable seasons has answered well; but Berberis Aquifolium and Darwinii are less satisfactory. Perhaps, however, by frequent planting they might become inured to transplanting, but it is likely to be at the expense of their healthy appearance. Rhododendrons and other American plants not being adapted for our soil have not been tried. A friend of mine, however, produced a very pleasing effect with the common Heath from a neighbouring waste. Single plants that had been cropped into a suitable shape by animals grazing them, looked tolerably well when introduced into the flower beds, and possibly other common plants might be found serviceable.

As the object of winter gardening is to present a furnished appearance in the flower beds from the time the summer plants are over up to the middle of March, when all are expected to be removed, it is obvious that the list of flowering plants during that period must be a limited one, and if the season should be severe, it is hopeless to expect much from this source; nevertheless, those anxious to make the attempt might try some of the earlier-flowering Primroses, of which the single white is the best I have—that being earlier under the same treatment than the wild one. Crocuses and Snowdrops, especially the latter, may also be planted, but it must be borne in mind that these bulbs rarely show themselves above ground till February; however, their cheerful appearance entitles them to a place in every garden. Winter Aconites transplant less satisfactorily, but I have not had much experience of them; and Hepaticas are too late for the purpose, as it is winter not spring decoration that we have in view; and if clearing the beds entirely by the middle of March be strictly adhered to, so as to have a six-weeks spring fallow, as it may be called, it is unpleasant to have to remove at that time plants that have scarcely attained their best.

Leaving, therefore, the subject of spring gardening for another occasion, I invite those who have had much practice in winter decoration and have employed other plants than those named for the purpose, to give us the benefit of their experience, as the matter is far from being so well understood as it ought to be. I have on former occasions described the mode in which we employ coloured materials, as well as plants, in our winter beds, so that the subject of polychrome decoration, as it has been called, need not be entered into here, further than stating that all who see it admit its advantages, and the great diversity it affords. In places where severe winters may be expected it constitutes an easy and pleasing mode of giving that beauty to a scene which the elements deny in another form. We only use materials of three colours—red brick dust, coal ashes for black, and a white sand plentiful in the neighbourhood, and I am not sure that more would be desirable. In large beds, however, another colour is worked-in with great advantage, and that is plain turf, which is made to form edgings to different compartments; or it may be cut into strips of 3 or 4 inches wide, and worked into a kind of embroidery or fancy work as may be thought desirable. Possibly, too, there may be other common things brought into use which have not yet been tried. The subject, although not new, has never yet become so fashionable as to attract the attention which it assuredly deserves, and which at some time it is likely to receive. I will, however, call attention to it on some future occasion.—J. ROBSON.

NEW GOLDEN COLEUSES.

THE utility of the Coleuses for ornamental purposes is so well known, and they can be so easily grown, and make such fine specimens in so short a time, that the value of those now in cultivation can scarcely be over-estimated. I wish to offer a few notes on them, to show how they have done with me during the past year as pot plants and as bedders.

I believe I am not wrong in saying that those previously sent out are of no value compared to the new golden ones. The new varieties differ from the others chiefly in their colours being the richest tints of bronzy crimson, with a peculiar lustrous glow.

I grow my plants mostly as pyramids in large 48-sized pots, and I keep them hard-pinched for the decoration of the dinner-table. Mixed with other plants they are very effective; under the chandelier they are perfection.

I think the variety, *Her Majesty*, the best I have ever seen; it has leaves as broad as one's hand, of a very deep bronzy red, and it very quickly makes a specimen.

Queen Victoria is a very beautiful variety; the centre of the foliage is of a rich bronzy crimson with a bright yellow edge.

Princess Royal is a lovely Coleus; the foliage is not particularly large, somewhat after the style of Queen Victoria, only brighter. The leaves are remarkable for the bright golden hue underneath. They have a most beautiful effect. Growing side by side you cannot see any difference from Princess Alice.

Telfordii aurea did not do well with me for the first year, though I tried several different ways of cultivating it. At last I have succeeded in growing it to perfection. I grafted it on Baroness de Rothschild, and during the last summer in my stove it was like burnished gold.

Of the other varieties, Princess of Wales, Prince of Wales, and the Duke of Edinburgh are very beautiful. Prince Arthur and Princess Beatrice are of a golden green hue, the principal veins being beautifully defined by crimson lines.

I have found the Beauty of St. John's Wood very handsome as a pot plant, and it is quite distinct from the old Coleus Verschaffelti.

During the past summer I bedded-out upwards of twenty varieties of the Coleus and only two did well—Coleus Veitchii and C. Verschaffelti. During the past summer I have visited several large public parks and gardens. At the Crystal Palace I noticed how very effectively and extensively Verschaffelti was used.

I have come to the conclusion that as pot plants in our stoves and greenhouses Coleuses are invaluable, but in our cold climate of England I believe I shall adhere to Verschaffelti and Veitchii for general bedding purposes. At the present time I have several specimens of Coleus Albert Victor and Baroness de Rothschild in 24-sized pots, and 2 feet in height. On these I have several different varieties growing. I have on one six or eight varieties growing, and upwards of twenty on one just worked. Their appearance is very novel and interesting. They are very easily grafted. I think it is very effective to see C. Batemani, with its nearly black foliage, grafted on a

bright golden Coleus. I hope to be able to report progress in the course of a few months.—F. P. L.

SETTING THE ROYAL VINEYARD GRAPE.

Last year I asked the cause of the bad setting of this Grape, and it was your opinion I had left too many bunches (eight). This I could not agree in, as the Vine was so strong, the rod, 6 feet from the ground, being 4 inches in circumference. Right or wrong, this year I have been successful in setting twelve large bunches. My method is simple—nothing new. I draw a dry hand along the bunch, or part of the bunch, when in flower, repeating the operation until the whole bunch is set. This answers well with all the Muscats I have, but the Royal Vineyard is more difficult to set, for with me it is never dry, a dewy wetness being on the bunches when in flower, making the hand damp and sticky. Having other Grapes in flower at the same time, I charged the hand with pollen and drew it over the Royal Vineyard, drying the hand every time, and every berry set; but when the Grapes had just finished swelling, having attained a good size, there appeared on some of the berries a blotch which had the appearance of a scorch. Scorching, however, could not occur, as the foliage was dense; in fact, the sun could not touch a berry. The berries so affected were at once cut out, but every day the disorder increased, so that by the time the berries not affected were ripe more than half the bunch was gone. The house is what we call our latest, and the crop is ripened without the aid of fire heat. We ripened Muscats in the same house, and to effect this we were obliged to put on fires. Can this have had anything to do with the disorder, as it commenced with the extra heat? Air was given night and day. Lady Downe's is in the same house, but is all right. One bunch of the Royal Vineyard was less affected and now hangs, being close to a front opening. It is one of our best-hanging Grapes, which is a consideration, and I do not like to condemn it if it can be successfully managed. I shall try it in pots next year. Will some of the readers of "our Journal" give us their experience of this desirable Grape?—C. M. McC., *Nash Court, near Faversham.*

[The berries of your Royal Vineyard Grape were attacked by "the spot," an ulceration usually caused by the roots not supplying a sufficiency of sap to sustain the growth of the Vine and its crop. If a little rich compost were placed over the roots, and weak tepid liquid manure applied once weekly during the season of growth, the spot would probably disappear. If the roots have descended deeply, or into an ungenial subsoil, they should be raised to nearer the surface.]

FLOWER SUPPORTS.

I have been a reader of your Journal for many years, and from it have derived a large amount of pleasure and knowledge, and as you invite all gardeners to record in it their thoughts and experience, a few remarks on the subject heading this communication I think may be of use to some.

Sticks are rather scarce, especially in or near towns; there, as is well known, are many gardens of small extent, the cultivators of which have not the privilege of going to a wood for a few sticks to which to tie their pet plants. To remove the difficulty I will name a plant which is not equalled for the purpose; it is of easy culture, and within the reach of most gardeners, and a great quantity can be grown in a small space. The plant is a common one in most gardens, but not grown so much as it deserves. It is the Halesia, or Snowdrop Tree, which enlivens our shrubberies with its beautiful snow-white drops in winter. Procure plants or suckers, or sow seeds in spring; select a piece of ground—they are not particular as to soil, any out-of-the-way place will do, but a moist one suits them best—plant them 1 foot apart, and cut them down to within 2 inches of the ground every autumn. If a few stronger sticks are wanted, leave the plants a winter without cutting, tie the shoots in bundles, and keep them in a dry place until wanted for use. If used green, as they emit roots so freely, they should be placed on a hot flue, or some such place, for a few hours. The quantity a few plants will grow is astonishing, and the sticks will last two years, and I am sure they are unequalled for tying such plants as Achimenes, Mignonette, &c. If allowed to grow in the shrubberies the plants are very ornamental, but when permitted to flower, and make large bushes, the quantity of shoots obtained is diminished considerably. Bees, too, are very fond of this plant, the flowers being numerous, and from them the bees gather a great quantity of honey.

Perhaps it will not be out of place to mention a few more plants from which useful flower sticks may be taken. If grown and cut down as above, many varieties of hardy deciduous Spiræas, varieties of Hypericum, or St. John's-wort, Ligustrum, or Privet, and Lilacs will produce an abundance of useful flower sticks.—H. C., *Hendre Park, Monmouth.*

GARDENERS' ELECTRICAL ALARUM.

It may be interesting to some of your readers to learn that the clever application of electricity is now becoming the gardener's friend, although for domestic purposes it has been employed for some time.

R. E. Thomson, Esq., J.P., of Kenfield Hall, Petham, near Canterbury, has recently had fitted up an electric apparatus, which surpasses even the electric house bell, which is now being extensively adopted in large mansions. The electric wire has now been fitted for the first time in Kent to all the greenhouses, hothouses, forcing pits, &c., at Kenfield Hall, and has been attached to thermometers in such a manner as to ring a bell in the gardener's room should any great change of temperature take place either from sudden frost or over-

heating. The electric thermometers are so arranged that the bell will ring when any degree of heat is reached at which they may be set. The invention is a very clever one, and must prove of great service to gardeners wherever glass houses are in use. It is patented by Mr. Saxe. The electric wire above mentioned is laid from the battery in the mansion, which was fitted up with the electrical bell and Mr. Saxe's patent indicating tablet two years ago. The importance of these ingenious contrivances cannot be too highly appreciated, and this application of electricity ought to made more known.—EDWARD COVENEY, *The Gardens, Kenfield Hall, Petham.*

GLAMIS CASTLE, FORFARSHIRE.

THE SEAT OF THE EARL OF STRATHMORE.

(*Continued from page* 415.)

GRAPES are at once the pride and the glory of Glamis, and not only of Glamis, but of the whole of Scotland. It was a proud day to Scotch gardeners generally, to Mr. Johnston in particular—the day of the late International Fruit Show in Edinburgh, to find that but with few exceptions the home productions had carried off the palm, no less than eleven of the first awards falling to the share of Mr. Johnston, he being first with every exhibition except one. Never was such signal success achieved, never were so many honours bestowed on any one individual in any special class before, and never, magnificent as our exhibitions have been, was there such a splendid exhibition of Grapes as that which was seen in Edinburgh in September, 1869. It is an honourable distinction at any time to obtain a prize for Grapes; it would have been glory sufficient to have obtained a single one in such a tournament, where some really good cultivators failed to find a place. How much more so, then, was this the case with Mr. Johnston, who, as it were, "cleared the decks" with his magnificent productions! How much of interest, also, is there not awakened within us as to the mode of their cultivation? Deeply interested as we feel in all that relates to the cultivation of that kingly fruit, the Grape, we paid our visit to Glamis to see and judge for ourselves, and report to our readers. We did not visit Glamis in the expectation of finding anything mysterious, or new and startling, in the method of Vine culture practised, and which had produced such splendid results, and we were not disappointed. Those, therefore, who may expect a revelation, we are sorry to doom to disappointment. Here we found no new theory or practice in operation, threatening to revolutionise our own, which we have yet a little faith in. Here we found no peculiar dogma, or narrow-minded crotchet as to the necessity of this or that precise method of heating, or this or that description of soil, &c., such as is often made to account for success. Here, however, we found in operation all that science and practice have recommended, in the broadest sense, for the well-being of the Vine.

So much discussion has lately taken place with regard to Vine-border making and heating, and even the adaptability of particular soils for our Vines, that we feel bound to make some remarks on these subjects.

First, then, we shall look at the borders at Glamis. They have been formed on the plan of those at Castle Kennedy, which, under the able management of Mr. Fowler, have proved so satisfactory. The first principle considered seems to have been ample scope for the roots. Borders are formed both outside and inside all the houses as far as we recollect, those inside being 16 and 18 feet wide, and those outside of a like, or probably greater extent. About that space of ground is, at all events, devoted to them, and in front, forming a margin to the walks running parallel with the houses, there is a pretty border of flowers, thus taking off the bare appearance of the Vine border itself—a practice which we most highly commend. We did not inquire about the depth of the soil or drainage. To the latter, however, we were informed very special attention was paid, as will be seen from the following particulars. First an abundant supply of brickbats and similar open materials was used, then near the top of this a series of transverse lines of open drain tiles were laid, communicating with the outer and the interior atmosphere. Such is called an aërated border, which means neither more nor less than a well-drained one, with the air passing to and from at the bottom, if it will, or when it is permitted. In this, some will say, lies the secret—aërated borders from henceforth! Here, however, they will be mistaken, for Mr. Johnston confessed to us that these air drains were blocked up and never used. Theory, which is often beautiful, called for an aërated border, and it was made; practice, however, has managed to beget success without it. One, and one only, of these Vine borders is heated—that from which Grapes are required for early spring use. It is heated in a very efficient manner by hot-water pipes below the roots, amongst the drainage, and Mr. Johnston is a warm advocate for the adoption of a heated border where very early forcing is required.

The soil of which these borders are composed is of a very light and sandy character, but remarkably full of fibre. It is simply some of the natural soil of the place, the top spit from some adjacent pasture, with a liberal admixture of ground bones and lime rubbish. No other manure excepting the bones was added, partly because none was at hand; yet look at the result. It is not the soil which one would naturally choose for making a Vine border. It seems far too light and sandy, and wanting in that soft silky texture which is generally so much of a desideratum. That it is a fertile soil we see by the abundant crops of grain produced in the district, and chemistry tells us that there is a large proportion of alkalies in the soil, caused through the old practice, not yet abolished, of burning the superabundant vegetation as it grows on the land, quantities of the ashes being thus intermixed with the soil; and "those soils," says Morton, "which contain a large quantity of potash in their insoluble portion, have within them a source of permanent fertility, the alkali being gradually liberated by the decomposition which is constantly in progress, owing to the air and moisture permeating the soil." We do not, however, attach very special importance to any particular kind of soil for our Vine borders, and this example at Glamis tends to confirm our views, that Vine soils have more to be considered with regard to their porosity and their permeability to air, heat, and moisture than anything else, with, of course, the necessary supply of food.

The vineries at Glamis are all on the lean-to principle which, although the oldest is, perhaps, the best and most suitable for general purposes, especially for a northern latitude; they receive and also retain more heat than span-roofed houses, the latter, however, having the advantage of providing a freer ventilation. Each of the houses is about 40 feet in length, and there are five of them, two of them being 22 feet in width, by 18 feet high at back and 5 in front, the other three being 2 feet lower at back. Ventilation is provided by moveable sashes in front, and at the back in the top of the wall; about 2½ feet being glass, with moveable sashes hung on a centre pivot and connected together, whereby the whole can be opened at the same time. These houses, then, as will be seen, are very spacious, thus allowing the Vines plenty of breathing air and head room, which contributes not a little, we believe, to their success.

The Vines are all planted inside the houses—one line along the front, with liberty for the roots to go to the outside, which they undoubtedly do; another line against the back wall. The distance apart is about 3 feet, or 3 feet 6 inches, and this, although greater than the usual width, has already proved too close to allow ample development to the enormous leaves and the robust character of Mr. Johnston's side shoots. The Vines planted in front are, of course, the principal occupants, although from those on the back wall some most magnificent fruit has this season been produced. They have, up to the present time, had a fair share of the direct influence of the sun's rays, but now, as the Vines on the rafters occupy the whole space, those at the back cannot be so much depended on, nor is it intended. We were informed by Mr. Johnston that during the months of May and June, 1867, the whole of these Vines were planted, some being from eyes raised the same season: so that in September last, when the fruit attracted so much attention, and was awarded so many prizes, the Vines which had produced it were little more than two years planted. Two years, rising three—let us repeat it again—the age of an ordinary pot Vine. The present age is a fast one, and in its Vine culture it does not belie its character. The Vines have all made most exuberant and substantial growth, and were in bearing last season on from 8 to 12 feet of their length of rod; the leading shoot, of course, having now twice reached its extreme limit. The mode of pruning practised is the ordinary spur system, the spurs or side shoots of this season being about the most robust we have ever seen, and with such foliage!—deep green, of the consistency of leather, and in the most perfect health. Mr. Johnston is a firm believer in the good offices of properly-developed leaves, to which he pays the strictest attention, and

it is needless to say, that without good foliage good fruit can never be produced, every particle of crude sap drawn up by the roots having to be elaborated through the agency of the leaves.

To describe minutely the occupants of all these houses, with the condition of the crops, would be unnecessary; we shall, therefore, just take a general survey, and note the most salient features.

The first house, then, which we enter is devoted principally to Muscat of Alexandria Vines, and nothing could exceed the general appearance of the entire crop, the average crop on each Vine being about 25 lbs. Some of the bunches were very large, probably weighing 7 lbs., and none under 3 lbs. The berries were large and very regular, perfectly ripened, exhibiting that beautiful amber tint which is alone the result of first-class cultivation. It may be remarked here, that to colour Muscats well, the berries require exposure to the full influence of the direct sun, quite the opposite to the requirements of black Grapes. Mr. Johnston is so well aware of this, and so much pains does he take to secure the desired finish in every part, that not content with the natural position of the bunch, he first exposes and finishes one side, and then turns the shoot with the bunch round and exposes the other. Thus a perfect amber tint is secured on almost every berry. In this house there is also an example of Gros Guillaume (Black Barbarossa), with some magnificent bunches and berries, some of the bunches measuring 22 inches in length. One bunch had been cut which was stated to weigh over 8 lbs.; its stalk only remained for us to see, and it seemed to be so exceedingly robust, that it was measured and found to be half an inch in diameter.

The house succeeding to this, third in the range, is called the early vinery, and is principally devoted to Black Hamburgh Vines. The crop, which had been ripe in July, was in great part over, although some fine bunches were still hanging quite plump and fresh, and the foliage as healthy and as green as grass. From five to seven bunches averaging about 3 lbs., were taken from each Vine. Here, then, is an example of Duchess of Buccleuch, one bunch on which measured fully 15 inches in length, and was very handsome, the berries of a perfect golden colour. This is, perhaps, the highest-flavoured Grape in cultivation, and is on that account a great favourite with Lord Strathmore. Mr. Johnston obtained the first prize with it in the competition for flavour at Edinburgh. It is just a little difficult to cultivate, and seldom to be seen in such perfection as with Mr. Johnston. Golden Hamburgh was here also doing well, with some fine fruit, and Golden Champion—the champion of all Grapes, was growing very vigorously in several places, where it had been inarched on the Black Hamburgh. This house being intended for early forcing, has the advantage of bottom heat, which is easily shut off or on at pleasure, by turning some valves in the interior of the house.

Retracing our steps on the right-hand side of the gateway, after passing through the stove, we enter a mixed vinery. Here some examples of Muscat of Alexandria were perfectly astounding, such bunches, such berries, such colour, as it is rarely our lot to see. Here, also, Mrs. Pince was doing well, and colouring well, which is very frequently far from the case. That noble-looking Grape, Black Prince, was likewise in fine array, and Muscat Hamburgh in splendid condition, without a trace of shanking, its besetting sin. Lady Downe's, one of the best of our late Grapes, was looking well, and some examples of the same on the back wall truly grand.

Next we come to what will ultimately be the late Hamburgh vinery, in which are at present some Fig trees, with only a few Vines. The first plant we noticed was a Black Alicante, and from this plant was cut the bunch which was considered the most handsome bunch exhibited, and which obtained the prize for the best bloom, at the Edinburgh Show. The two or three bunches which still remained were certainly models. On the back wall were fine examples of several varieties, including Duchess of Buccleuch. The next house, which is also the last, is termed the late vinery, being filled with examples of Lady Downe's; Black Alicante, which, for appearance, is excelled by none, and for flavour, when well ripened, not a long way behind; Raisin de Calabre, a coarse white sort, superseded now by Thomson's White Lady Downe's; and Black Morocco, a truly handsome sort when well set and well managed, as it is here, but which in ordinary circumstances is quite worthless, owing to its bad setting qualities. Besides these, the permanent occupants of the houses, we observed in several of them, along the sides of the pathway, pillar Vines in the border bearing splendid fruit. Some we observed had been cut down to the surface of the ground, the stump only remaining. On inquiry, much to our astonishment, we were told that these were pot Vines—Vines in pots plunged in the borders which had been used to provide a supply of fruit for the past three years, until the permanent Vines could do so. Never have we seen Vines in pots bearing so prodigiously—Muscats some 3 lbs. in weight, with eight and ten bunches on a plant, &c. The roots had, of course, extended beyond the pots into the soil of the border; yet so little was it the case, that they were still *bonâ-fide* pot Vines. It is a lesson worth knowing—how to provide a supply of Grapes at little expense, until the work can be performed by the permanent plants.

Having now passed in general review all that relates to the Vines and Vine culture at Glamis—having laid the plain facts before our readers, it might be well before we close to see if we cannot, from this very successful example of Grape cultivation set before us by Mr. Johnston, learn a lesson for our future guidance. The idea that first-class Grapes could not be cultivated thus far north, is happily proved to be erroneous. To what are we to attribute Mr. Johnston's great success? Is it to the houses themselves? No, although they are all that can be desired. Is it to the construction of the borders, their drainage, aëration, or the quality of the material? It is not to the first, although that is no doubt good, nor to the second, which is not used. It is, however, we believe, somewhat owing to the fine quality of the soil used, its great openness and freeness of texture; and in a large measure to its great extent, and the liberty which the roots have had, as well as to the corresponding scope for the development of the top—thus root and branch have been in a corresponding comfortable medium; and, lastly, chiefly to the assiduous care of Mr. Johnston, in providing at the proper time the requisite degree of heat, moisture, &c. In short, it seems that care and attention, with very liberal treatment in every respect, are the principal wants of the Vine. This is what the Vines have had at Glamis, which has made them the glory of the land, and Mr. Johnston the prondest, although at the same time the most unassuming of Grape cultivators.

(To be continued.)

ROSE STOCKS.

As the planting season extends from now to February, a few remarks on stocks may be acceptable to your readers whose land is similar to my own—sandy.

For the last three years I have invariably planted below the collar all my worked Roses, either on the Manetti or Dog Rose. Now, some will say those worked on the Briar would perish; granted in strong soils, but in sand I have always found during the hot summer months that planting thus is much better, and keeps the roots from burning.

I have a plant (name lost) budded on the Briar, with a stock 18 inches long, which is quite below the surface, yet it is in a flourishing condition. I have a Gloire de Dijon on the same stock against a wall planted in the same manner, and it is a large tree and very healthy. In our land nothing answers so well as the Manetti. You have fine heads to your trees the first year, when those on the Briar make but little wood and require years to form a tree of any considerable size.

I have one old tree of Jules Margottin, budded on the Manetti stock, which I have had occasion to remove for alterations; its stock measured 3½ inches in diameter, and the roots measured as many feet in length. Talk of the stock wearing out, I do not think it ever wears out, but improves as it becomes older. If Roses are budded low, I find after a few years some part of the tree has made roots for itself, and, if the stock do wear itself out, your tree does not perish.

If amateur growers follow my plan, say for one year, I think if they have many Roses on the Briar they will lower their stocks for ever afterwards. Of course these remarks are only intended for dwarfs. I have a Maréchal Niel and Monplaisir on a new stock, the name of which I have lost and forgotten. Perhaps you can help me.—Amateur.

[We can but guess that the stock of which you have lost the name is Gloire de Dijon.—Eds.]

American Peach Orchards—How they are Raised.—The stones of the fruit are planted in the fall, come forth as young trees the following spring, and are budded the first year, as soon as the season will admit. By good cultivation the trees

will often show fruit the third year, bear a full crop the fourth year from the bud, increase in fruitfulness for about seven years, and as soon as the fruit gets at all smaller and later than usual, they are cut down, and succeeded by fresh plantations in other parts of the farm: so that a Peach-growing farm is a succession of plantations, from the stone to the decaying tree. Of course, the land, after the removal of the decaying orchard, undergoes renovation and rest by manure and other crops, until the ground, in the course of years, is able by restored fertility to bear a new plantation.—(*Toronto Globe.*)

DESFONTAINEA SPINOSA.

It is much to be regretted that in a great many public ornamental grounds care has not been taken to introduce our choice shrubs in larger numbers. Cemeteries give scope for a greater variety of shrubs than are often found there, and it has frequently occurred to me that no better place could be chosen for them, for many of the visitors need something that will interest and not offend them, and a more fitting object could not be found than a shrub with which the visitor is, perhaps, not acquainted. Laurels, Laurustinus, Lilacs, and the like, good and indispensable as they are, need not be the only shrubs planted, there being many others known and cultivated long ago that are far from being common even now. It is but seldom that the Phillyreas are met with, and no finer shrubs are grown than some of them; they always look well, and sometimes, when loaded with berries, are quite handsome. The glossy-leaved Alaternus is equally ornamental.

As, however, I may shortly call attention to these and other neglected evergreens more fully, I at present merely press the claims of a rather tender evergreen of more recent introduction on the attention of cultivators. I refer to Desfontainea spinosa, a shrub in many respects resembling the Holly, only instead of being ornamented with berries, red or yellow in winter, it presents us in summer with an abundance of handsome orange-coloured flowers, resembling those of Lapageria rosea. The plant, I believe, is perfectly hardy, but ought to be classed amongst those flourishing in peat soil, more so, I think, than the Magnolia and some other plants. It is, nevertheless, more accommodating than some of them, and is well adapted for a low wall; but here a plant on the open lawn flowered most profusely during the past summer, no doubt stimulated to this by the hot dry weather of the previous year. With us the plant is not fast-growing, but this I attribute to the lack of peaty matter in the soil, as I have seen it elsewhere grow more freely. To those who have not seen its fine, orange-coloured, tubular flowers, and who have a favourable position for a plant of moderate growth, I would say, Obtain one of this, and the first appearance of its blossoms will be an ample reward for any trouble that may be taken.

I believe it likes a dry situation, but I am not sure of this; still, as for plants of doubtful hardiness such a position is the safest, we must take it for granted as being the best for the Desfontainea, until, perhaps, some one finds out that one quite the contrary is better. Those places where I have seen it succeed were dry, and sheltered from the coldest winds.—J. Robson.

PLANT-PROTECTORS—BRICKS versus WOOD.

The advantages which Rendle's protectors offer are probably not overstated, but as it is invariably claimed for these and other miniature glass coverings that they are cheap and durable, it may be worth while to inquire whether, if we accept the invitation and regard them from an economical point of view, some modified form could not be had, which, in addition to being really cheap, might be as applicable to the same purposes with nearly the same advantages. When this thought occurred to me, I went to the carpenter who does what work is required here, gave him the dimensions of Rendle's largest protector, which is 8 inches high in front, 12 inches high at the back, and with the glass 24 inches wide, and I inquired at what price, to afford himself a fair profit, he could supply a protector of a similar size, with glass of the same quality (21-oz.), but with 1½-inch deal boards instead of the bricks; the boards to be grooved, painted twice, and thoroughly finished off. In his estimate he has given me the price of the planks, painting, and glass separately, but it will be sufficient for my purpose to say that his price is 1*s.* 4*d* per running foot, or a trifle more than half the cost of Rendle's protectors. This does not include the ends, which could be supplied at 9*d.* each.

Now, without wishing to detract from the merits of the brick protectors, I would ask, Is not this simple modification worthy of attention? I think it is. In comparing one with the other, the only advantages possessed by the bricks over the boards, as far as I can see, are their power of absorbing and retaining heat, and their greater durability. Nor would I consider the latter to be of much advantage; for stout planks, with a very small annual outlay for paint, will remain serviceable for a long course of years.

The introduction of protectors for sheltering tender vegetation is evidently a step in the right direction; but while we heartily acknowledge this, it will be well to bear in mind that in order to ensure general adoption they must possess simplicity of form, economy in price, and efficiency when in use. The brick protectors undoubtedly possess these qualifications in some measure, but I think that for many purposes, and certainly in all places where the soil is at all uneven, the boards will prove the more useful.—Edward Luckhurst, *Egerton House Gardens, Kent.*

THE KALES OR BORECOLES.

I have seen at Messrs. Barr & Sugden's grounds a heavy trial of Kales, and the following observations made there may aid in rectifying the mistakes made in the names, and keep matters straight for a year or two.

Taking Mr. Cattell, of Westerham, as an authority, he being looked upon by the trade as better acquainted with the Kales than any seed-grower or seed-seller, Mr. Barr had from him a large-leaved lightish green plant, as *Buda Kale;* a dark bluish-green leaved plant, a little in the same way, but more vigorous-growing, as *Egyptian Kale;* a somewhat curled-leaved Kale, one purplish and the other green, as *Jerusalem Kale;* a plant, apparently a sub-variety of the Jerusalem Kale, as *Delaware Kale;* and for *Ragged Jack* he had a plant of recumbent, spreading growth, with large darkish green, much-cut leaves. Now this dark green Egyptian he has had from other houses as Buda, with, perhaps, a sprinkling of the lightish green in it. Query, are they one and the same thing, but selections?

From France came a Kale very much like this Egyptian, but with a smaller leaf, called *Chou à faucher*, and, if I mistake not, I have seen this same kind of Green growing wild on the seacoast.

In referring to catalogues, I find Chou de Milan, Buda, Egyptian, and Jerusalem Kale all candidates for the name *Asparagus Kale.* No doubt they are all sprouting Kales, and this must be their principal advantage, but which of them should be called *the* Asparagus Kale? Some authority ought to speak out, so that the trade may be somewhat agreed. Some of the trade send out for Asparagus Kale *Couve Tronchuda*, an excellent vegetable, but certainly having no claim to the name Asparagus. Sea-kale Cabbage would be an appropriate name for it.

In the spring I asked Mr. Duncan Hairs if he could put me right about Asparagus Kale. He said he knew the Kale well, and would give me a pinch of seed. I sowed it, and it proved to be Jerusalem Kale according to Cattell, and certainly at the present moment about its shoot there is more that would claim the cognomen "Asparagus" than the varieties of other Kales I have just named.

Mr. Barr, from another source, received seed as *Lapland Kale*, which proved also to be Jerusalem Kale. He also received some seed as Miller's Winter Kale, which proved to be Egyptian Kale. From a third seedsman he had Ragged Jack, an upright somewhat laciniated Kale. He had the same Kale from another source as Ragged Jack.

Of those popular Kales I therefore make out as different:—

Buda—large, broad, lightish green foliage.
Egyptian—large, broad, somewhat cut, bluish green foliage.
Jerusalem—erect and branching or sprouting, somewhat curly.
Ragged Jack—erect and laciniated.
Delaware—in the way of Jerusalem, but a little different.
Lapland—same as Jerusalem.
Chou de Milan—long, thick, vigorous, with large leaves, and showing promise of abundance of sprouts.
Cottagers' Kale—in the same way as Chou de Milan as to growth, but differing in colour and in foliage.

It would be very desirable if their true names could be affixed to these Kales, and a good descriptive note attached to each. Then there is the *Prussian Kale* and *Siberian Kale*, which it would be well to fix to their right varieties. Besides

those that I have named, there are the Marrow-stemmed, Thousand-headed, Palm-formed, &c.

Curly Greens also want looking to a little. I do not see the true Dwarf Curled Kale of my boyish days amongst all the varieties I have, nor yet that strong-growing tall Kale, which the lads and lasses used to steal blindfold, to see what sort of husband or wife they were to have, and which was always enough for a good strong boy to carry on Hallowe'en night.

The varieties in this way of English or Scotch that Mr. Barr has, are mostly intermediate and from France; they are so dwarf as to lay quite on the ground, indeed, they squat themselves on the soil. Then there is the *Canadian*, which has a drooping, arched foliage, and some others. One firm for Chou de Milan supplied Savoy seed one year, and when it was mentioned to them they persisted they were right, and so they were to a certain extent. Chou de Milan, according to Vilmorin's "Plantes Potagères," is the generic name for Savoy; but Chou de Milan in the London trade is a different thing. Now, here is a field, and dealing with a subject of this kind we ought to bring ourselves somewhat in harmony with our French neighbours, for anyone sending to Vilmorin for Chou de Milan would no doubt get Savoy seed.—F.

ROSES AND THEIR STOCKS.

Much has of late been said on the various stocks on which to cultivate "the queen of the garden." Everybody loves Roses, and, as in other cases, so with the Rose, we cannot accept or adopt one universal mode of culture. Circumstances have much influence over the successful culture of Roses, and respecting stocks for them much practical information has of late been advanced, and much light has been thrown on the subject, which no doubt will prove useful and acceptable. We have one extolling the Briar as a stock, and as deliberately condemning the Manetti, and the contrary; others advocate different kinds of Roses for stocks—all useful in their way no doubt, and perhaps suitable to the circumstances under which each advocate is placed; but, at the same time, it should be borne in mind, that the vendor is supposed to have something of all kinds to meet the requirements of those who may give him a call.

Much has also been said respecting the merits of both old and new Roses. There can be no question about many of what are termed "old Roses," holding their own against all comers. There is also a wide difference between growing Roses for exhibition and for decorative purposes. This should always be borne in mind, so that under these circumstances there must be a resort to different kinds of stocks; all Roses will not in all places succeed under the same treatment, so that neither one stock nor any one mode of culture can be adopted—let each under his or her peculiar circumstances take notes and act accordingly.

From past experience I long ago discarded Briar stocks and standard Roses, but I would not advise others to do so, if such answer their purpose.

I find, where I am situated, that the Manetti stock when properly treated answers my purpose better, on the whole, than any stock I have tried; but notwithstanding all the stocks and modes of culture advanced, I prefer all Roses that will succeed on their own roots. By frequent transplanting they form almost a mass of roots, and it is astonishing to see the growth some of our best Perpetuals make on their own roots. This season we have had shoots of Charles Lawson, one of the very best of Roses, from 6 to 8 feet in length, likewise Princesse Mathilde and the Rev. H. Dombrain, besides many others of equal growth. Acidalie, a Rose that is not much known, but one of our very best white Roses, has yielded us a profusion of beautiful bloom. This I attribute to stopping the early summer's growth, which was unusually strong.

During the Rose season that has just past, very many of our best Roses have rewarded us with a profusion of blooms which in quality and richness of perfume could not be surpassed; but while those which are called new and exhibition Roses are brought so prominently before us, and shown in all their beauty (and they are worthy of all the praise), I would ask, Is there not a culpable neglect of others of the same race, which deserve some share of our admiration and attention? I mean those glorious old favourites, the China Roses, which are well adapted to every place, though they have to be remembered as the neglected ones. They are a numerous race, and many of them, whilst very distinct in colour, are in form not to be despised.

While I commit these few remarks to paper, under a cloudy dull November sky, what can be more charming than the display of the China Roses of various colours? But, why are they neglected? Did not one of our contributors recently say something about their worth in the shrubbery border? I add, they are worthy of that, and better places too. I need not say one word about properties, their qualities, or the mode of propagation, because they can be readily increased.

While on this subject, I would ask why that gem is so seldom met with, which ought to be in every garden—the double yellow Rose, called the Persian Briar? When well grown (and it is very accommodating), there is not its equal in colour. I have had it succeeding well on the Briar, on the Manetti, and on its own roots. Though its flowers are of short duration, it well repays any amount of labour, and for aught I know, it will succeed everywhere.—M. H., *Acklam Hall, Middlesbrough-on-Tees.*

FORCING PLANTS.—No. 5.

Rhododendrons must be admitted to be the princes of evergreen flowering shrubs. They are easily forced, but to flower well ought not to be subjected to great heat; indeed, they ought to be brought forward slowly. A greenhouse with a night temperature of 40° is sufficient excitement for the first three weeks; then afford a steady increase of temperature to 45° and 50°, which is sufficiently high for bringing them into bloom. The house cannot be too light and airy, but a moist atmosphere must be maintained until the blooms expand, when a drier and cooler atmosphere is more suitable.

The plants need no previous growth or preparation in pots, only for forcing it is desirable to make an early selection in order to secure those which have the growth and buds formed earliest, as they will be most suitable for early forcing. They ought to be in pots at the close of September or beginning of October, and should be at once placed in a cool airy house. They will be very suitable for forcing early in December, for flowering in the middle or end of January. They move, however, with such excellent balls that they may be lifted as required, potted, and placed in the forcing house at once, but it is desirable to let them remain at least a fortnight or three weeks in a cool house before being placed in artificial heat. The balls are sometimes inconveniently large; they may be reduced so as to fit a moderate-sized pot, but this must weaken the plants, and, if carried too far, will result in a weak bloom; it is well, therefore, to preserve as many of the roots as practicable. Peat soil alone is a suitable compost, though a mixture of turfy loam, leaf soil, and old cow dung answers very well. Good drainage must be provided, and care should be taken in potting not to leave any vacancies round the ball not filled-in with soil. Good supplies of water are needed, and a gentle syringing morning and evening will do good, discontinuing it when the trusses show colour.

After flowering the plants should be continued under glass, and be kept safe from frost until danger from it is past, when they may be planted out, or continued in pots, plunging them in an open situation, and giving a top-dressing or mulching of cow dung, with abundant waterings in dry weather. The earliest-forced plants seldom form flower-buds, but those which have been but gently forced will for the most part do so, and they are the best plants possible for early forcing. Most of the plants will be again available for forcing after a year's rest; but they come in so well for filling gaps in shrubberies that they are mostly planted-out, and others selected in autumn for forcing. Plants wintered in a cool house and allowed to bloom naturally without fire heat may be grown year after year, and a selection of Rhododendrons in pots affords a fine display during March and April, and ought to have a place in a cool house or an orchard house. There protection could be afforded to this class of plants, whose flowers are subject to injury from the spring frosts that in our climate are accompanied with such an amount of moisture as to vastly impair the beauty of the bloom. Some of the best sorts for forcing are:—

Dwarf or Small-growing Rhododendrons.—Azaleoides odoratum, white, shaded with purple, very fragrant; Ciliatum, white, delicately shaded with rose, sweet-scented; Daphnoides, waxy rose; Dauricum atrovirens, purple, very early, forcing well in November for Christmas bloom; Gemmiferum, shaded crimson with white centre; Myrtifolium, rose. These sorts are splendid

for bouquets and general decorative purposes, being in every way smaller than the other kinds.

Early-flowering Rhododendrons.—Of these Nobleanum may be taken as the type. They bloom so early that the flowers are injured by spring frosts. Broughtonianum, rosy red, splendid for a cool house; Campanulatum hybridum, white; Caucasicum album, white, plant dwarf; Mars, vivid scarlet; Marian, pink, dark spots, dwarf close habit; Nobleanum, scarlet, rose, and several other varieties; Nobleanum superbum, scarlet, very dwarf, and very early; Rosamond, rose, very dwarf; Russellianum superbum, deep scarlet, large truss; Stamfordianum, rosy scarlet; and Wellsianum, scarlet. These are excellent for permanent culture in pots, and are the best of the large-flowering kinds for forcing. If not excited by more heat than that of a cold house to which no fire heat is given except in very severe weather, they bloom well annually for a great many years, and are fine plants for the greenhouse or conservatory.

Catawbiense Varieties.—These are very hardy, have immense trusses, and the flowers are of good substance, hence they are well adapted for forcing. Album grandiflorum, blush white, green spots; Azureum, bluish lilac; Cœruleseens, bluish purple; Everestianum, lilac, spotted and fringed; Fastuosum flore-pleno, lilac; Grandiflorum, deep rose; Roseum elegans, pale rose; and Roseum superbum, deep rose.

Late-flowering Hybrids.—These are good forcers, but ought not to be excited much before January, and they flower best if allowed to come on slowly in a cool greenhouse. Those named are of dwarf good habit. Alarm, white centre, edged with light scarlet; Blandyanum superbum, light crimson; Brayanum, rosy scarlet, with light centre; Brilliant, crimson scarlet; Coriaceum, white; Lefevreanum, purplish crimson; Maculatum purpureum, purplish rose, much spotted; Madame Miolan Carvalho, perhaps the best white Rhododendron; Neilsoni, rosy lake; Ochroleucum, pale yellow, brown spots; Paxtoni, rose; Victoria (Pince's), deep claret; and William Downing, dark puce, blotched.

Azaleas are second only to the Rhododendron, and they have the advantage that some of them are scented. The small-flowered but very sweet kinds, as Viola odora, orange and salmon; Viscosa floribunda, white; and Viscocephala, sulphur white, are splendid both for pots and cut flowers. The pretty A. amœna, rosy purple, is fine; and so are Monstrosa fasciculatis, yellowish orange, and Monstrosa variabilis, yellowish orange, but changeable on account of their dwarf habit. English varieties:—Coccinea major, dark scarlet; Decorata, pink; Pontica varieties:—Alba (Thompson's) creamy white; Macrantha, sulphur; Princeps grandiflora, pink; and Triumphans, orange. Ghent varieties:—Coccinea speciosa, orange scarlet; Julius Cæsar, red, orange in the upper segment; Morteri, yellow and rosy red; Princesse d'Orange, salmon pink; Quadricolor, buff, shaded with salmon; and Unique, deep scarlet.

The Azaleas require the same treatment as Rhododendrons. They may be forced a month, or, better, six weeks after the leaves have fallen, potting as soon as they begin to fall, or in October.

Andromeda floribunda is a good free-flowering plant, and being white and sweet-scented is fine for bouquets. It requires but very little forcing. To have it in flower at Christmas plants that have been potted in September or October, and kept in a sheltered position or cool house, may be placed in a house with a night temperature of from 40° to 45° at the end of November, and they will be in splendid bloom at Christmas. It is naturally so good in habit that it must be considered a first-rate decorative plant, and it is one of the most effective of hardy low-growing shrubs when gently forced. It requires a more sandy peat than Rhododendrons, and should be grown in partial shade during the summer, and be well supplied with water. Return it to a cold pit after flowering, and harden it well off before exposure out of doors. The plants may be grown a number of years in pots, and annually placed in a cool greenhouse for blooming. There are many species of Andromeda, but A. floribunda is the best.

Kalmia latifolia, with good foliage and splendid heads of bright rosy scarlet flowers, is a fine forcing plant. Small plants well set with bloom buds should be potted in October, kept in a cool house, and be forced the same as Rhododendrons. To succeed well they should not be subjected to a high temperature, but be slowly brought forward. The plants may be grown in pots for a number of years, but they will not flower the second year if they are forced early, and usually are only available every second year. The variety myrtifolia is a dwarf form with much narrower foliage. It is very handsome. Soil, sandy peat, and good drainage. Standards of K. latifolia are fine for large conservatories, and for decorating halls, &c.

Daphne Cneorum.—The flowers of this are very sweet, and deep pink or rose. It may be had in very small plants. The way to obtain them is to layer a good branch of an old plant in a 3 or 4-inch pot in autumn or spring—for a dwarf plant layer it close to the shoots—plunging the pot in the ground. The following autumn the layer will be well rooted, and may be detached and potted in a 6-inch pot, plunging it in a warm dry situation. Pinch off the bloom next summer, and keep the plant duly supplied with water. It should have an open sunny situation. The soil used may consist of sandy peat two parts, one part loam, and one part limestone or lime rubbish, with a free admixture of sand. Good drainage must be given. The pots ought to be set on rough cinders, and the intervals between the pots filled up with the same. The plants are impatient of stagnant moisture, therefore guard against its lodgment by raising them above the ground level. By autumn they will be fine plants; remove them to a cold pit before severe weather sets in, and take into the forcing house a few plants at a time, placing them in a light and airy situation, and near the glass. They succeed in a greenhouse, and require nearly the same treatment in forcing as Rhododendrons. Standards are very handsome, and they are obtained by layering a branch with good shoots well situated for forming a head. After layering the branch and securing it with a peg, put in a neat stake, and tie the branch upright to it. Detach the layer a year afterwards, and grow it a twelvemonth in a pot as described for dwarf plants. The stake, being no thicker than the stem, and painted green, will not be very conspicuous. Standards in 6-inch pots are very ornamental for table decoration.

Viburnum Tinus (Laurustinus).—Flowering as this does in winter, it can hardly be said to be forced, but as the flowers are liable to be injured and retarded by severe frosts a few plants in pots are desirable. The plants are best grown as pyramids or standards, both of which are handsome, the latter especially so when on stems 24 or 30 inches high and having compact heads. Either are easily formed by cutting in to the shape wanted in spring before they begin to grow, and disposing the shoots equally in summer, not stopping any except those which are very strong, as from their points the bloom is produced. Standards take a longer time to form, but they are of easy formation, the side shoots being taken off until the length of stem required is secured. They ought to have an open situation out of doors from May to November, being well supplied with water in dry weather. A cool, airy, light house from which frost is excluded, is all the forcing they require.—G. Abbey.

NOTES AND GLEANINGS.

We are informed that the prize of £5 5s., offered by Lieut.-Col. Scott, R.E., Secretary of the Royal Horticultural Society, for an Essay on the Principles of Floral Criticism, will be awarded on Wednesday, May 4th, 1870, and not January 19th, as previously announced.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Little can be added to previous directions under this head; operations at this season are entirely dependant on the state of the weather. No opportunity should be omitted of getting the soil in a favourable state for the reception of the various crops which must soon be committed to it, and as the basis of success is allowed by all good practical gardeners to be a thorough system of drainage, no time should be lost in attending to this. The surface of the soil must be occasionally stirred amongst *Cauliflowers*, *Lettuces*, and young *Cabbages*, and the earth should be drawn round plants of the last to prevent them from being blown about by the wind. *Celery* and *Parsley* must be protected in severe frost. See that a warm patch of ground, on a south border, is in readiness to sow a breadth of early *Radishes*, and in bad weather prepare a quantity of material for the protection of early crops of various sorts.

FRUIT GARDEN.

The renewing of fruit-tree borders where the soil is impoverished is very necessary at this season. Let as much of the old soil be removed as can be done without disturbing the roots, supplying its place with maiden loam. Avoid stimulants, which often induce over-luxuriance instead of fruitfulness. As a considerable difference of opinion exists on this

point, young gardeners will do well to turn their attention thereto. As far as my experience goes, I hold it to be a great point in the formation of borders for fruit trees, that no stimulating manures should enter into their composition. I ought to add, however, that Vines are an exception, for they are gross feeders, and capable of taking up and assimilating a greater amount of nourishment than harder-wooded fruit trees. All the pruning, except that of Figs and Apricots, and most of the nailing of wall trees, as well as the training of espaliers, should be finished, if possible, by New Year's-day, and the same may be said of bush fruit. The making of borders or stations for fruit trees, too, should be autumn business; indeed where new soil has to be introduced, October is the most fitting time, as the best of soils may be seriously injured by moving them in a wet state. All matting or bast required for the ensuing year should be cut, sorted, and hung up ready for use. No time should be lost when the weather is bad in proceeding with in-door work. Besoms and baskets should be prepared, the tool-house examined, and any other work done that is possible.

FLOWER GARDEN.

When any of the beds or borders require a dressing of fresh soil, this should be in readiness to wheel on in favourable weather. As a dressing for flower-beds, fresh soil is in most cases preferable to manure, which is apt to cause too luxuriant a growth for a first-rate display of flowers. In soils naturally poor, however, and where neither fresh soil nor decayed leaves can be had, a moderate dressing of well-rotted farmyard manure will be useful, but this should be thoroughly mixed with the mould the full depth of the bed, and not carelessly turned over and left in lumps near the surface, for in this case a gross habit of growth would be promoted early in the season, and as the principal parts of the roots would be near the surface in the manure, the plants would soon feel the effects of dry weather; but if the manure be well incorporated with the soil to the depth of about 18 inches, no ordinary amount of dry weather will injure the plants after they once become fully established. Attend to the protection of tender plants, and in moderate weather like the present, especially if dry, open the canopies or coverings a little for a few hours once a-week or so, in order to dispel damp. A plan of the masses or beds might also be decided on. As regards florists' flowers, little can be done now except in the way of preparation, and should frosty weather set in, it will afford the opportunity of having all the compost heaps thoroughly frozen; by repeatedly removing the encrusted surface and piling it up every morning, many of the insects and their eggs will be destroyed, a point of no small importance to the cultivator. Hard weather is also a good time to cart turf, peat, &c., and to lay in for the various plants and flowers a good stock of the soils most suitable, without which it is next to impossible to grow such successfully. If leaden pegs are used for layering Carnations, a fresh stock may be cast, and the old ones cleaned and straightened. If the florist can mend his own hand-glasses and shades, these ought now to be looked over, and the metallic wires which have been used for attaching the stems of Carnations or Tulips to their supports should be made ready for use, and stored away in their proper places. During severe weather rabbits will be apt to attack Carnations and Pinks. It would be worth while to try the plan of dipping small square pieces of cloth in brimstone, tying them to sticks, and inserting the sticks in the ground round the beds.

GREENHOUSE AND CONSERVATORY.

As the introduction of Chrysanthemums must have caused a disarrangement of part of the stock, it is of importance to set the plants which have been removed in their former situations, or to rearrange the whole, so as to produce a good effect. Plants, however, must not be set where they will not thrive, and this is a point to which careful attention must be paid. Chrysanthemums decaying should be cut down, if that has not been already done. They should then be suffered to become somewhat dry, and be removed to cold frames. Those who cannot afford frame room, may secure them in some shed or outhouse for a few weeks, covering them overhead with clean straw whilst frost lasts. If they are slightly frozen it will not matter, only take care that they do not thaw too suddenly. The present dry, cold weather may cause extra protecting material to be employed, therefore some should be in readiness when required. If not already done, lose no time in placing under cover a supply of the various loams, peat, &c., likely to be required for spring potting. The conservatory and show house should now be made as gay as possible with forced plants; keep up a regular succession throughout the winter and spring, by bringing forward stock as wanted. Roses, both dwarf and standard, Honeysuckles, hybrid Rhododendrons, and Azaleas, with many other plants, will enable cultivators to make a good show. Hyacinths, Narcissuses, Tulips, Lily of the Valley, and similar flowers, must be forwarded as wanted. Hard-wooded plants will require a rather dry atmosphere, in order to keep them free from mildew and damp. The principal work in plant houses will consist in keeping them and their inmates scrupulously clean.

STOVE.

Little can be said with respect to stove plants at present. Use moderation in heat, ventilation, and atmospheric moisture. Beware of exciting the buds of Orchids too soon. Attend to this, and keep a somewhat drier atmosphere until the middle of January.—W. Keane.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

The past has been for the most part a week of mist, fog, and rain, making the ground, if at all stiff, slimy and uncomfortable on the surface, and therefore but little digging and trenching was done, leaving such work until we had a little frost, or the weather should be more open, and drier. Where, however, other work was scarce, rough digging, and especially ridging-up, could be proceeded with. In the frosty days, when not engaged in ice-collecting, we were chiefly employed in wheeling manure into heaps, whence it could be taken as needed, collecting soil and tree leaves, and taking up more Sea-kale and Rhubarb, and placing them in the Mushroom house. The first has come in very well with little or no bottom heat, the heat of the atmosphere ranging from 55° to 58°. Our first bed of *Mushrooms* has yielded well, helped by some manure waterings of dried cow dung soaked in water. Woodlice nibbled a few Mushrooms, but they seem to have all left us, after pouring very hot water down the small chinks made at the backs and fronts of the beds, where they congregated to screen themselves from observation. We never hesitate to use hot water in such places, as it benefits the bed rather than otherwise; but we have not yet gone the length of giving a watering all over a bed, young Mushrooms and all, with water nearly at the boiling point, as a friend of ours does, and he says with the best results. The farthest we have gone in the way of experiment was to water a yard or two with water at 195°, and though there were a few Mushrooms some 4 inches in diameter, and plenty from the size of peppercorns and walnuts up to the above, we did not see that the warm water did them any harm. Still, as we generally have plenty without such extremes, we would be inclined to let well alone, except in the way of experiment. Had we a bed that did not bear, or ceased to bear prematurely, and we thought the barrenness might be owing to coldness and dryness, we would not hesitate to make some small holes, water well with warm water, draw a clean spade over the surface, and cover to keep the heat in, and thus induce a fresh gentle fermentation. We have acted thus on several occasions with good results, but that is a different affair from using water nearly at the boiling point to a bed bearing as our friend's does, or at least did lately, and he is no new beginner, but a grower of many years' experience. Until we know more, we would not counsel the free adoption of the practice, as some have tried it and been unsuccessful. Still, some of our readers may try as an experiment how high a temperature the Mushroom will bear for a short period, as in such hot-watering. We know it will often stand a low temperature, as we have gathered Mushrooms when covered with snow; and from beds out of doors that were supposed to be exhausted in November, and stood, therefore, exposed all the winter to frost and the general run of the weather, we have gathered lots, and a crop came again plentifully in April. Still, to obtain regular crops, it is well to attend to the systems of culture generally adopted, and recommended in these pages.

Radishes, Cauliflowers, Endive, &c., protected from the frost, are still good, and opportunity was taken to collect a lot of *leaves*, which were at once thrown into shape for frames, and which will yield a sufficient heat ere long to advance *early crops of Radishes, Carrots, Potatoes, Turnips*, &c. These leaves will heat and subside all the more regularly if no soil be put on until that subsidence has taken place, and as no turning-over to sweeten will be necessary, much labour will be saved if the cart can be emptied at once where the beds are to be. Moveable frames with sashes are exceedingly useful for such pur-

poses, and will serve many turns in the course of a season. For such temporary purposes, the frames are best to be shallow and light—say 9 inches high in front, and 15 inches at back, as they can stand above the soil, &c., in the bed, be easily raised at the corners to give more room to the plants inside if needed, and be easily moved. A good slope to suit the winter is secured by making the back of the bed much higher than the front.

Much of the refuse and cleanings from the garden come in very useful for the bottom of beds when they do not form part of the rubbish-heap. Many things from the garden when decaying would yield a valuable heat for various purposes whilst fermenting and decomposing, and there need be no fear of bad steam if such rough beds be covered with from 6 to 9 inches of half-decayed, rather dry old hotbed dung. If it be necessary to help on in such frames, plants in pots in winter which are liable to *damp* in moist weather, that will be greatly prevented by a covering of dry ashes from a furnace, or from the house fires, kept dry on purpose. A few lumps of unslaked lime will assist in this and do no harm whatever. It is astonishing how little air will keep such plants dry on the top and comfortable under such circumstances, even in close damp weather such as we have lately had. The little heat beneath, but from which no steam and but little vapour can rise, enables one to give air more continuously, and that continuous air-giving is more important than sliding off the sashes partly or altogether in a fine day. When the plants become inured to the change the more sunlight they can have the better, if the weather is mild; and when plants are hardy, except to frost, the lights may come off for a short time in the middle of the day. Robust health will greatly depend on the cleanness of the glass, and especially when rough coverings are used. Hence, in drizzling but not wet days, much time was taken up in washing sashes inside and outside. We fully concur with what a correspondent lately said about the importance of neat substantial coverings for protection, and the cleanliness and the tidiness thus secured about pits and frames. Still where much of this kind of work is to be done, and neatness for a time must be sacrificed to utility, nothing is so economical as rough litter for meeting all cases of extremely cold weather. Even then it is well to have a close covering next the glass to keep it clean, but that must be often dispensed with.

By attending to the details given last week, many things here shut-up and covered-up for about a week during the frost, looked when uncovered just as if they had been covered-up for an ordinary night. Of course, this would not have been the case if they had been helped with artificial heat.

Sea-kale.—Many amateurs with little room will thank Mr. Record for his plan, detailed in page 452. We force a good quantity in pots, as the heat can be easily regulated—more easily than when the roots are placed at once in a bed. When such plants come in faster than we want, the pots can be moved to a cooler dark place. But for this moving, and when amateurs come to know what a bed of a certain size will do, a small bed covered with any old box will afford much cutting. Such a box without a bottom and with a moveable lid set over the plants would be an improvement over covering a pot with another pot of the same size, as the atmospheric heat would be more equal. The instructions about raising from seed are very good, but, as stated, fly and other intruders are very troublesome. When once a crop is forced seedlings will be less needed afterwards, as the roots, gradually hardened, and cut up into pieces of 6 inches in length, make excellent plants and grow strongly. Practical papers, such as Mr. Record's, will help to bring this luxury in winter within the reach of the many having small gardens. With the roots packed in pots and boxes, we have known of many fine dishes obtained with no other help than darkness and the vicinity of a kitchen fire.

FRUIT GARDEN.

Much the same as last week, only we turned aside the light covering placed on the Vine borders in the end of autumn, removed the now rotten mulching that had been given in summer, slightly forked the ground just to break the surface, gave a sprinkling of bone dust, a little fresh soil, 2 or 3 inches of horse droppings as a mulching, and then about 1 foot of warm leaves to communicate a little heat to the soil, and to be used as a bed for Strawberries, covered with old sashes to give them a little start for houses, pits, &c. With the early covering of Vine borders with dry litter or fern, there would be little necessity for much fermenting material even for early forcing, as if the covering were put on, say about the end of September, the sun's heat during the summer would be prevented escaping. Though we had only a few inches of litter and leaves on the border, scarcely 6 inches, and loose and open, the heat of the soil in the border was fully 10° higher than in the open ground at 6 inches from the surface. Much injury, we believe, has often been done by huge mounds of hot fermenting material. There is a common opinion that heat rises and will not go down, but it does go down by conduction, as may easily be proved by placing sticks and thermometers in the soil at different depths in covered borders. Much may be done and with perfect safety by preventing the escape of the heat given to the soil by the summer's sun, and when hot fermenting material is used, it is safest to use it in moderation. The heat should not average more than 75° at from 4 to 6 inches from the surface.

We looked over late Grapes, and the fruit in the fruit room, where, on the whole, it is keeping better than last year, and Pears are unusually rich in flavour. The heat and the dryness were too much for them in 1868. Many trees were much injured by the dryness, and no waterings could be given them. The heavy rains of this afternoon (the 11th) will be a great boon to this part of the country, as water was anything but plentiful.

ORNAMENTAL DEPARTMENT.

In wet days much time was taken up in cleaning, picking, potting, &c. A few tree leaves enabled us to raise our frame beds higher from the ground, as those on the ground level containing forward Mignonette, &c., were beginning to show some signs of damp. A higher position where the plants could get more light made them all right. In all plant houses, as well as frames, there has been little occasion to look after atmospheric moisture, as the evaporation from the pots and the soil was quite enough in such misty weather. Even if now we should have brighter weather, less artificial vapour will be needed if we lessen our fire heat when we can obtain sun heat. By giving little air then, and that early, we do not give such free opportunity for the moistest air to escape, and, therefore, do not require to secure so much vapour artificially in the atmosphere of the house. This becomes a question of economy in houses kept at a rather high temperature, as it should never be forgotten that in obtaining moist vapour from a heated surface, you so far cool that surface, and, therefore, the more the vapour raised the more fire needed.

During this weather in all cold pits and frames, and in all houses heated merely to be safe, great care should be taken in watering to water only when required, and to spill or drop as little as possible. In the case of plants in pits and frames, where there is a dry surfacing to help to secure a drier atmosphere, and only a few plants need watering, it is safest to lift the plants out, and only replace them when the excess of moisture has drained away. Such things as Calceolarias and Cinerarias rarely suffer from a damp standing-ground or a moist atmosphere.

Flues.—Thanks to Mr. Robson for the article on flue-heating, page 456. We may expect more inquiries about them. We know that his round cement pipes answer admirably. We forget whether they pass under the doorways or not. There is no difficulty in this when the chimney is high enough. When the chimney is short it is better that there should be no dip. We find that what we have said of small outlet pipes from a stove in a house has led to misconceptions as the size of a pipe that could be taken from a furnace to act as a flue round the house. The two circumstances are entirely different. We would, therefore, be obliged to Mr. Robson and others to let us know the smallest diameter of a pipe that they have known to act well as a flue from a furnace. Six inches is the smallest bore we have known to act at all well, and that in a small house, and we would recommend that flues should never be less than 8 inches. As we have had many inquiries as to the small flues lately alluded to under the floor, part of the tiled floor forming the top of the flue, we may say that, inside measure, they are close on 5 inches wide and 8 inches deep, as the three bricks-on-bed have very narrow joints. These flues have no plastering inside or outside, except the joints, and the crossing the joints as described at top, as the heat of such simple flues tells mostly from the exposed surface. Where stability and economy in material are great objects, we believe that two bricks-on-bed would give a good flue. We think, however, that when a third brick is used, as with us, the draught would be rather more free, and there would be less necessity for frequent cleaning. We have never had much soot in ours when cleaned even at long intervals.

In reply to others, we would say that with good, sound, well-burned bricks, well soaked before being used, so as to take firm

hold of the fine mortar at the joints, we would have no plastering over the sides of the flue, either inside or outside. A correspondent tells us that the inside of his flue was carefully plastered with a composition of fine lime, cow dung, and other things, and that certainly it looked neat and smooth; but every now and then there is an explosion, and the bad gases pass into the house from pieces of the plastering falling down and arresting the draught. At the next cleaning we would clear all such plastering out, and if the bricks were at all ricketty, plaster the ontside instead. With good bricks we would plaster neither inside nor outside, and the flue will give out the heat of the furnace better. We may state, in conclueion, that in the case of such flues in temperate houses, they may be made wider than we have stated if the tiles for covering are also wider, but the width stated will be enough for ordinary-sized houses.—R. F.

COVENT GARDEN MARKET.—December 15.

Owing to the absence of orders from the provincial markets, business remains dull; and heavy stocks of winter goods are now accumulating. Quotations remain nearly the same as in previous reports. Hothouse Grapes and Pines are more than sufficient for the demand. Pears comprise Winter Nelis, Glou Morçeau, Chaumontel, and St. Germain. Apples are chiefly Newtown Pippin, Blenheim Pippin, and Nonpareils. Of Potatoes there is a heavy supply.

TO CORRESPONDENTS.

*** We request that no one will write privately to any of the correspondents of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely to The Editors of the Journal of Horticulture, &c.*, 171, *Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

Annual Subscription (*Cincinnati*).—You will have seen in a notice published by us a few weeks since, that the subscription for a year is 17*s.* 4*d.* For that sum it can be sent to Cincinnati or other parts of North America, weekly, and post free.

Our Journal at Liverpool (*A Reader*).—If you have any difficulty in obtaining the Journal from your bookseller, apply to the nearest railway bookstall, and by paying your subscription in advance you can always have it regularly either at Liverpool or elsewhere.

Planting Roses on the Manetti Stock (*Poplar*).—"You have planted your Manetti Roses rightly, by placing the junction of the scion and stock 2 inches below the soil's surface, and they will do well in your light loamy soil. You can put on your marl or manure over the roots now, and draw the earth over it like a molehill. In the spring spread and fork your ground level. Manetti-stocked Roses like the ground to be moved often. The hotter the weather the more frequently it should be moved. Prune in the spring, say February or March. Cut the shoots from the base of the plant to different lengths if you wish for a bushy plant.—W. F. Radclyffe."

A Myrtle not Bushy (——).—The cause of the Myrtle cut down being badly furnished with shoots, is, perhaps, the shoots having grown long without stopping. We would cut the plant back in spring—each shoot to within 6 inches of its base, some being cut-in shorter than others, so as to form a compact plant. This would be best done in spring before the plant begins to grow. A compost of two parts light loam, and one part leaf soil or sandy peat, with a free admixture of sharp sand, will grow it well.

Acorn Growing in Water (*Idem*).—The acorn may now be placed in a glass or bottle filled with water to within half an inch of the acorn; put it in a dark closet for three weeks or a month. The small end should be placed downwards. Covering the acorn with a little moss will facilitate growth by keeping the acorn more moist.

Laying Turf and Gravel (*Idem*).—Turf may be laid any time from September to May in moist and mild weather, but we prefer doing it in autumn and early in spring. We consider gravel is best laid down in March; the walks are then made trim for summer, and we may calculate on weeds not troubling us much before the close of summer.

The Canadian Representative Plant (*Ebor*).—Your friend is quite correct—the Maple leaf is the badge of Canada. This is told in the national song of that dominion.

"On merry England's far-famed land
May kind Heaven sweetly smile;
God bless old Scotland evermore,
And Ireland's emerald isle;
Then swell the song, both loud and long,
Till rocks and forests quiver—
God save our Queen, and Heaven bless
The Maple leaf for ever!
The Maple leaf, the Maple leaf,
The Maple leaf for ever;
God save our Queen, and Heaven bless
The Maple leaf for ever!"

Seedling Apple (*W. H. Caparn*).—Your seedling Apple, Pickering's Seedling, is very good. The flesh is tender and delicate, the flavour excellent, with a nice aroma; and it is a good-sized handsome Apple.

Shrub Seed Sowing (*Poplar*).—The small cone sent is that of some of the Arbor-Vitæ family, but which we cannot say. The seeds, if there were any, had fallen out. They are not unlike small Apple pips, and if they are sound and plump you may gather them now, keeping them in a cool dry place until March; then sow them in sandy soil in a pan, and place them in a cold frame, keeping them moist, but not very wet. When the seedlings appear admit air freely, and in spring pot off singly, growing them in pots for a time, and then plant them out in the open ground in a sheltered position.

Apple and Pear Pips Sowing (*Idem*).—At the end of February or beginning of March sow them in the open ground in moderately rich light soil, scattering the pips rather thinly, and cover them about half an inch with finely pulverised soil. In a year or two the seedlings will be fit to transplant, and in the third or fourth year they will be fit for budding or grafting.

Cutting-back Magnolia grandiflora (*Devon*).—You may cut the Magnolia back to the height required, at the end of March or the beginning of April, but though you would secure a dwarfer plant for a time, it would not flower until it attained the height you name; indeed, if the plant be of good shape we strongly advise you to let well alone. We cannot name Aloes from leaves.

Removing Cinerarias from Cold Frames (*Idem*).—The plants ought to be kept in the frames as long as you safely can on the score of frost, as they are more healthy and compact in growth than when grown in heated structures and at some distance from the glass. Without heat we do not consider Cinerarias safe in frames after the beginning of November, and we should house them forthwith.

Cutting Down an Old Laurel (*H. D., Kent*).—Now is not a good time to cut down a Laurel. It ought not to be done until March, or, if the spring is cold, not until the beginning of April. Leave as much young wood as you can from the base of the plant.

An Arbor-Vitæ Bare at the Bottom (*Idem*).—Your only plan will be to tie what shoots you can into the bare places, distributing them so that with succeeding growth the bare places will be filled up. Probably by tying-in you may take away much of the loose open character of the tree. Removing the surface soil down to the roots, and replacing it with turfy loam, leaf soil, and old cow dung would give increased vigour. It may be done from now to March in mild weather. A few good soakings of water during dry weather in summer would do good.

Lilium auratum not Flowering (*M. H.*).—Perhaps your plants are not sufficiently vigorous for blooming, but we advise you to have the plant potted at once, removing most of the old soil as far as that can be done without injuring the roots, placing it in a pot sufficiently large to hold the roots without cramping them, and to allow for growth. A 9-inch pot will be large enough for an ordinary-sized bulb, though for a good-sized bulb it is not too large. Drain the pot well, and allow for top-dressing the plant in spring with rich compost. A compost of two parts fibrous loam, one part each sandy fibrous peat and leaf soil, or old cow dung, will grow it well. Keep the pot cool during the winter, and in a place free from drip, not setting it under stages, as is too frequently the case. The soil should be kept moist, and frost ought to be excluded. A cold pit or cool house is the best place to grow it in, affording it a light, airy position. Now is a good time to purchase plants in pots, but to buy bulbs earlier in autumn is preferable. It is not too late to pot Tulips for greenhouse culture, but they are far better potted at an earlier period.

Peat (*Ignoramus*).—The peat sent is fit for fuel, but quite unsuited for plant culture. Peat for gardeners' purposes is chiefly woody fibres with sharp siliceous sand intermixed.

Burning Charcoal among Plants (*J. C. M.*).—You will have seen what we said in answer to other correspondents last week. No fuel of

any kind can be burnt for any period among plants, unless there is a flue to carry off the fumes resulting from the combustion of the fuel, without causing the leaves to become yellow and fall.

Flower-Garden Plan (*A Young Beginner*).—In "Flower-Garden Plans" are drawings exactly suited for you, the forms of beds, plants for them, their arrangement, and culture. You can have it free by post from our office if you enclose 5*s.* 4*d.* in postage stamps, with your address.

Meteorological Questions (*Fairylike*).—These are not within our province, you had better write to the editor of some meteorological periodical.

Address.—A gentleman wishes to know the address of Mr. Pannell, formarly of the Renshaw Ironworks, Chesterfield.

Size of Iron Wire for Cordon Training (*T. T.*).—"Galvanised-iron training wires should be of size No. 10. At every 4 feet is needed a galvanised iron peg, with an eye for the wire to run through, and 4 inches in length for stone walls, and from 2½ to 3 inches long for brick walls. A long screw and nut will draw 200 feet quite tight. Should you wish to try the French "*raidisseur*," or tightener, you can then have thinner and cheaper wires and more of them. Instead of 12 or 15 inches interval, you may have 10 inches, which will not be too near for close pruning. These little raidisseurs are cheap (some cost only 3*d.*) and effective. There are several kinds, all fairly good. That exhibited in 1867 in the gardens may prove the best. Messrs. J. B. Brown, of Cannon Street, London, used to supply them in large quantities. Soft lead wire is a luxurious tie. The hard-frozen trees were, perhaps, rather precipitately planted. Gradual thawing is safer, but it is wonderful what trees will bear. The nature of the soil in which they now stand will much influence their recovery if warm and open. Protect the roots carefully from frost and cold drenching rains. Maiden cordons under glass can be pruned now, except in hard weather. But why not wait till February? If they are in the open air, by all means wait. Peach trees require more heading-down than Pear trees, as a rule, because one-year-old dormant buds of the Peach are not easy to move. Only equalise the points of Pear cordons the first season, and cut back in the winter.—T. C. Bréhaut."

Applying Soda to Fernery Rockwork (*A. E. F. C.*).—It is not safe to apply a solution of soda to the rockwork of a fernery, as it will destroy all the foliage it touches, making it quite black, and will injure the roots of many Ferns. We do not think it would kill slugs and caterpillars without injury to the plants. You may capture the slugs by searching for them at night with a lantern, and the caterpillars may be taken by day. They will be found secreted among the foliage.

Manuring Pelargoniums (*Idem*).—Remove the surface as deeply as you can without injury to the roots, and replace it with a compost of equal parts of fibrous loam, leaf soil, and old cow dung, or well-decomposed manure, raising it an inch or two higher than it was before. It would be quite early enough to do that in February, but you may do so now if you wish to encourage growth at this season.

Ornamental Water Plants (*A Subscriber*).—There are no "Lilies" with blue or red flowers that are hardy; but there are several besides the white Water Lily (Nymphæa alba) and yellow Water Lily (Nuphar lutea), but these two are the best of each genus, and, except for variety, others are not particularly desirable. Villarsia nymphoides, with heart-shaped leaves, and umbels of yellow flowers in June and July, requires deep water like the Nymphæas. Richardia æthiopica, well known as a pot plant, is hardy if placed deep enough in the water to have the roots beyond the reach of frost; the flowers are white. Calla palustris should be planted near the margin. For Alisma Plantago, flowers white marked with purple, 1 foot of water is required. Butomus umbellatus, flowers pink, in umbels on a long stalk, requires from 1 to 2 feet of water. Iris pseud-Acorus, reed-like, with yellow flowers in June, needs from 1 to 2 feet of water. Ranunculus aquatilis, white flowers early in summer, should be planted near the margin. Caltha palustris, and the double variety, with yellow flowers in May and June, should be planted on the margin. Menyanthes trifoliata, with white flowers in July, should also be planted on the margin; Lysimachia thyrsiflora, with yellow flowers from May to July, is also suitable for the margin; Hottonia palustris has flesh-coloured flowers appearing above the water, the plant entirely submerged, and requiring from 1 to 2 feet of water. Aponogeton distachyon, with fragrant white flowers, is one of the finest of aquatic plants, and in 1 foot of water it is quite hardy. It flowers from June to October. Others are Sagittaria sagittæfolia, white flowers from June to August, 1 foot of water, leaves arrow-shaped; and Stratiotes aloides, white flowers in June, 1 foot of water. In planting, all that is required is to secure them erect in the mud at the bottom. You will find a more extensive list in pages 225, 247, 312, and 330 of vol. v., New Series, as well as cultural hints.

Weeping Willow (*S. S.*).—"The good old Weeping Willow" you require is the Salix babylonica. The Kilmarnock Willow has larger leaves. Any nurseryman could obtain them for you.

Grapes and Pears (*G. B. F. S.*).—We think that your Muscat Vines are perfectly healthy. The Grapes you sent are over-ripe, and passing into the state of raisins. The wood not being quite ripened merely indicates that a little more heat should be given. Your Pear No. 1 is Beurré d'Aremberg. The other Pear was smashed and undeterminable.

Clinkers Forming Rapidly (*Devon*).—The greater the draught and the quicker the combustion of the coke, the more likely are clinkers to be formed. The making the coke small will not prevent it. Mixing the coke with blocks of wood would lessen the evil, and so would using coal that has little bitumen, and burns to a white ash without leaving a cinder. Where clinkers are an annoyance such coal would be an advantage, and the greater quantity of smoke would be lessened by a small aperture to admit air over the fireplace.

Hypocaust Heating (*A. B.*).—What we understand by hypocaust heating, is heating from beneath, and we do not think it signifies how the heat is obtained, if it is obtained and equally diffused. Heating from a furnace without pipes or flue would do as well for Pines as any other mode, provided the smoke could not come in contact with the roots of the plants, and more especially could not by any possibility escape into the atmosphere of the Pine house.

Weymouth Pine (*J. R. P.*).—Seventy-two feet in height, and 15 inches in diameter at 3 feet from the ground, are not extraordinary dimensions for the trunk of this tree grown in England. It is of slower growth here than in North America, its native place, where it attains a height of 150 feet. The timber it makes is called Canadian white pine and Punkin pine. In America the wood is more employed than that of any other Pine, and in the Northern States masts are exclusively made of it.

Management of an Ice Pit (*P. W. Fairgrieve*).—We rather question the propriety of the Fir branches at the sides of the earth pit for ice, they are so apt to enclose air. If anything, clean straw would have been better, or nothing at all, letting the ice come close to the earth. Then the keeping of the ice will mainly depend on the exclusion of wet and heat by the thatching, and this would be improved by letting the thatch come over the ground for a width of 4 feet all round. The ice would be still safer if there were a narrow trench 3 feet from it, as deep as the pit inside, and that made airtight by the thatching passing over it. The heat of the summer would then little affect the earth immediately round the pit. For ourselves we have been as successful with mounds entirely aboveground as when the ice was altogether or partly sunk in an earth pit, chiefly because the thatching kept out heat, and all moisture passed easily away. Nothing melts the ice so soon as confined moist vapour.

Removing Strawberry Leaves, and Old Raspberry Canes (*E. B. P.*).—We would remove no decayed or other leaves from Strawberry plants in the open ground until all danger from frost was over. Even then they will soon be out of sight and be covered by the young growth. The sooner the old bearing canes of Raspberries are cut down close to the ground the better. The bearing wood of last summer's growth should merely be shortened a little according to its strength, say from 3 to 3½ and 4 feet. The smallest should be thinned out.

Heating by a Stove (*C. B.*).—We do not think that any mode of heating by gas would be less expensive than by Joyce's stove, neither would it be safe. Strong argand burners in such a stove would be the most likely to answer in so small a greenhouse, and we should think would be safe if a small gas-pipe were taken from the top of the stove into the open air. There is this trouble with all stoves with prepared fuel, that one may run out of fuel when it is wanted most. A small stove ought to heat your house (15 feet by 9), and keep its temperature above 32 during all the frost we have had. You may say you cannot have a flue, but you might have a pipe 3 inches in diameter passing from your stove into the open air, and then you could burn coke or common cinders. Could not the Joyce's stove be so altered?

Heating from a Boiler at the Back of a Dining-room Fire (*J. F. C.*).—Your proposed plan will answer very well, of course with a rise of 8 inches from the boiler to the small tank. The top of the boiler will require to be close, not open. The front exposure of the boiler in the fireplace would do, more especially if the fire play on the bottom as well as the front. The tank, though small, should be divided, and the flow-pipe enter at one side and the return come from the other side. Iron will be the best material for the tank for your purpose, but wood sides would retain the heat longer, and, covered with iron or slate, would give you enough heat at the top. You would require to have a small box over the tank, with room for at least 3 or 4 inches of sand or other material to plunge in, and from 4 to 6 or more inches above that to let the cuttings grow. Cover with a small frame of glass, moveable, so that you can reverse the sides, upper and lower, as often as you need. For your tank, 3½ by 2½ feet, we would have a little box 7 inches deep in front, and 10 or 12 inches deep at back, and have two squares of glass in slight frames to cover it. These moveable, you can reverse them whenever the inside surface becomes damp, and thus avoid all wiping the glass. The tank should be 4 or 5 inches deep; it would be of little use were it deeper. With fire in the room all the evening the heat will be quite enough. In very cold nights you might pack the cinders in front of the boiler.

Flue-heating a Greenhouse (*D. J. D.*).—See "Doings of the Last Week," page 423, only below the line in italics, instead of "top" read "bottom" of flue. To make sure the depth there given is ample; there ought never to be less than 18 inches difference between the grate bars and the bottom of the flue. See also page 456 on heating by a flue. Our impression is, that the reason your unglazed pipes will not heat except close to the furnace, is, that your pipes are too much on a level with the furnace bars—not raised enough above them. This you could easiest remedy by sinking the furnace. Possibly also the furnace, which you say is large, may be too large for the size of the pipes. Such pipes should at least be on a level until they reach the chimney, and better still if there be a perceptible rise all the way. Possibly, too, the pipes and chimney have become filled with damp air, which needs to be dislodged. If you could make a small fire at the bottom of the chimney, where most likely you have an iron plate for sweeping, that might make a keen draught, and if so the flue-pipes would draw well afterwards. If you cannot do that, light some dry straw or shavings, small wisps, and place them burning down the open end of your iron chimney, repeating the dose several times, and immediately afterwards burning such dry stuff and dry wood in your furnace. If your furnace bars and pipes are right, most probably the smoke and heat will go along the pipes afterwards, instead of coming back and out at the furnace door. We should give these simple remedies a trial. In fresh-made flues, and flues long unused, we have had frequently to light a fire, as above, in the chimney, to draw out the damp heavy air. If these remedies do not answer, then there is something wrong in the position of the flue. If so, were we in your case, as the house is so small (15 feet by 6 feet), and the brick furnace is large and built inside the house—though fed and attended to from the outside, the furnace, as we presume, against the back wall—we would be perfectly satisfied with turning that furnace into a stove, making it from 3 to 3½ feet or even 4 feet in height, covering the top with tiles, a flag-stone, or an iron plate, and making a hole in the back wall 9 inches from the top, to be connected with your short iron chimney. With close-fitting doors, and a small ventilator in the ash-pit door to regulate draught, you would be sure to have enough of the latter, and plenty of heat to keep out any frost, and you would have no trouble with flues, or sinking the furnace. Meanwhile, as you have the pipes, try the above simple modes for encouraging a free draught. If you can keep an average heat of 45° at night, except in very cold nights, when the temperature of the house may fall 5° lower, you may easily have a few flowers all the winter. For instance—say that the winter extends from November to March, you can have for the first two months Scarlet and other Pelargoniums, Chrysanthemums, Chinese Primulas, Cyclamens, Heliotrope, Polyanthus, Violets, Mignonette, Wallflowers, &c. The bulbs would come in after Christmas; and from December onwards there would be of shrubs, Camellias, Ericas, Epacrises, Cytisus, Coronilla, Daphne indica odora, China Roses, Myrtles, &c.; also, such Fuchsias as serratifolia, and such

Tropæolums as Lobbianum. We would have entered more into details, but as you wish to have a book recommended, we would advise you to obtain "Window Gardening for the Many," from our office, price 9*d.*, or free by post 10*d.* You will there find minute details how to treat these plants, and the only difference would be that you have better chances than any mere possessor of windows. If you want any definite information we shall be glad to give it. Meanwhile, as a beginner, do not be disheartened; the best and simplest instructions will never teach you so well as your own practice, and, rightly looked at, a failure is often as valuable a teacher as a success. It was not kindness to lead you to expect crops of Grapes so soon after planting the Vines; and by the way, with Vines in such a house, it will not be advisable to have the temperature higher than 45° with fire heat all the winter.

Vinery Flue-heated (*W. B. B.*).—The door is to be in the south end, and the house is to be against an east wall, with a walk, we presume, from the door at the south end and along the east front merely. As the south sun will strike only on the end of the house, such a house will not do so well for Muscats as if it had a more southern exposure, but it will do. The flue, if single, should come in at the south end facing the doorway, or low enough there to come in beneath it, go along the front, and cross the north end to the chimney. If the doorway were reversed to the north end, we should propose the flue to enter there in preference. If you want much heat better have the flue above ground. The border had better be made the full breadth of the house. The Vines may be planted in front, if fully 6 or 9 inches from the flue, if the pathway is latticed; but if the pathway is solid the Vines had better be planted against the back wall and brought down the roof. The flue above ground will not interfere with the Vine roots. If you supported the front of the house on arches or piers, the roots could run outside; but 8 feet wide, with rich top-dressings, would keep the Vines prolific and healthy. With such a sandy bottom you would do well to brick it as you propose, or concrete the bottom, place over that 6 or 9 inches of open rubble, with a drain in front, and then from 18 to 24 inches of the best fresh fibrous loam you can find, and in such a border mix with it 6 cwt. of broken boiled bones, about one-tenth part of lime rubbish, and an equal amount of very rotten sweet dung. More bones may be used if boiled and merely broken. They will afford nourishment for a long time. The Grapes named will suit each other, but they will be late, and require more heat than such kinds as the Black Hamburgh and the Sweetwater.

Raspberry Planting (*Vicar*).—Your proposed plan of planting is very good, if the rows are at least 5 feet apart, but a rail 2 feet high will not be sufficient after the first season. We would recommend you instead to have stout elm posts 4 feet out of the ground—say 3 inches in diameter, and from 10 to 15 feet apart, and on these fasten two rows of wires one-twelfth of an inch in diameter, one 18 inches, the other 3 feet from the ground. The simplest way to do this is to straighten the wire by pulling it round the bole of a stout tree, then place one end against the first stake at the right height, drive in an iron nail close to it, say 3 inches long, for half its length, then bend the other half and knock it down firmly over the wire, and so with all the rest. Run a tar brush over the wire, and when dry tie the stems to it. You will soon save in ties the price of the wire over a rail. Of course, iron posts and stays, and wire properly strained, would be better and neater, and, perhaps, as economical in the end; but as you spoke of having a rail, we merely mention the above mode as a great improvement, and being also more economical.

Vinery Roof and Planting (*Merlin*).—Giving the height of a house 9 feet at back and 6½ feet in front, will not enable us to say exactly what the slope would be, as that slope would be different in a house 7 feet wide, from what it would be in one 12 feet wide, being much flatter in the latter case. If the half or so of the front upright were glass, then if the house were 11 or 12 feet wide, the roof would throw off the rain, and the perpendicular light would be so useful that the house would do well for general purposes. How can we tell the number of Vines you should plant, as you say nothing of the length of the house? We can speak more definitely of the kinds in an unheated house, as Black Hamburgh, Black Champion, and Black Prince, White Frontignan, Buckland Sweetwater, and Royal Muscadine. For Vines alone, and a moderate width of house, the Vines may be planted 4 feet apart; but as you wish to have Peaches, Figs, &c., you may have Peaches and Nectarines against the back wall, and Peaches and Nectarines in pots on the front border. For these to do well, the Vines should be 6 or 7 feet apart when established. For the back wall, select such Peaches as Bellegarde and Noblesse, and such Nectarines as Elruge and Violette Hâtive, and for pots or tubs, or trained to a low trellis, such kinds as Royal George, Barrington, and Walburton Admirable Peaches; Downton, Rivers's Orange, and Hardwicke Nectarines; and such Figs as Brown Turkey and White Marseilles. If you heat the house a little, the same plants would do, but if fond of the Muscat flavour, you might have the Muscat of Alexandria in the warmest place, the Muscat Hamburgh anywhere, and Trentham Black. We are sorry to say, however, that we have little faith in your proposed mode of heating. The simple fire-brick furnace 3 feet below the ground level is all right enough, but the two 3-inch pipes, one from each side going round the house and out at a corner, are a very problematical affair. These, if at all horizontal, would, we fear, soon clog up, and require constant looking to, even if fuel producing little smoke were used. We have little faith in flues placed horizontally, if not fully the double the diameter proposed. From 8 to 12 inches in diameter would be safer for cylindrical pipes. See answers as to stove and flue-heating to-day, and pages 423 and 456. The Pelargoniums referred to in page 366 were packed firmly in earth, watered, surfaced as described with dry soil, but all the tops were left exposed. The lime and charcoal on the cut parts were to prevent bleeding and decay.

Reineckia carnea (*Schubert*).—It was introduced by Mr. Evans, of Stepney, from China in 1792, and was then called Sanseviera carnea, or S. sessiliflora. It is a Liliaceous plant of the sub-order Aloeæ. It was flowered for the first time in the January of 1803, by a firm then at Kensington, Messrs. Grimwood & Wykes. They cultivated it as a stove plant, but it is said to be nearly hardy. We shall be obliged by information relative to its culture by those who have bloomed it.

Muscat Trovéren Grape (*J. Anderson*).—It is best known as the Trovéren Frontignan. It is an excellent Grape, requiring as high a temperature as the Muscats. We cannot tell the parent of the grub without seeing a specimen.

Pears for Double Grafting (*Centurion*).—Try any of the following which are arranged in the order of the value we set upon them:—Doyenné du Comice, Maréchal de la Cour, Marie Louise, Alexandre Lambré, Glou Morçeau, Jargonelle, or Citron des Carmes.

Chrysanthemums Flowering Imperfectly (*Roche*).—We should think it arises from the plants being weak. Not having sufficient water and support in summer would cause it; or it may be a result of the plants being kept too warm and close in the greenhouse, or of the roof being shaded and covered with climbers. A dozen good large-flowering Chrysanthemums are:—Flenr de Marie, White Beverley, and Rotundiflorum, whites or blush; Lady Talfourd, Pink Perfection, Fingal, rose-coloured; Hercules, Ossian, and Lord Clyde, or Purpureum Elegans, purple and crimson shades; Golden Beverley, John Salter, and Guernsey Nugget, yellows. They are rather new, but not very expensive.

Training Gouros against Walls (*A. T. F.*).—The Gourds may be trained against walls, but not well without a trellis, though by careful tying and nailing you may probably keep the Vines from breaking. They would require to be raised in a hotbed in spring, and be put out, when strong well-hardened plants, at the end of May. Abundant supplies of water will be required in dry weather. We think the other two you inquire about would require glass. We have no experience of them out of doors.

Names of Fruits (*G. Godbold*).—We cannot name the varieties of florists' flowers. Your Pears are:—1, Beurré Diel; 2, Napoléon; 3, Nouveau Poiteau. The Apple is Pearson's Plate.

Names of Plants (*A. R. C.*).—Libonia floribunda. (*Miss Sophy Webster*)—Your Dendrobium most probably is D. chrysanthum, the other Orchid is Zygopetalum Mackayii. Send us your Conifers again when convenient, and we will do our best to assist you. (*W. M. B.*).—2, Blechnum occidentale; 3, Adiantum cuneatum; 4, Asplenium, probably A. dimorphum; 5, Diplazium sylvaticum. (*Mary K.*).—Your flower is that of Aspidistra lurida. The flowers are always produced round the base of the leaves close to the soil. (*J. Turner*).—Your Conifer is the Cedar of Lebanon. (*R. W.*).—Nerine undulata. (*J. K.*).—Your Orchid bloom was dreadfully crushed when it reached us, so we can merely guess at it. We believe it to be Epidendrum cochleatum. (*W. C.*).—Your "Blechnum" proves to be Doodia caudata. (*A. Lee*).—Hakea semiplena, with entire leaves; Hakea purpurea, with three or four-partite leaves. (*R. L.*).—Your Orchid spike is certainly that of a Cymbidium, and we think, also, of the species C. bicolor, but you give us no information as to its foliage, or whether its spikes are drooping or erect. The flowers had changed colour, but so far as we can tell, it is identical with Cymbidium bicolor. (*A. W. Mirfield*).—Oncidium barbatum.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending December 14th.

Date.	Barometer.		Thermometer. Air.		Thermometer. Earth.		Wind.	Rain in inches.	General Remarks.

POULTRY, BEE, AND PIGEON CHRONICLE.

VARIATION OF COLOUR IN POULTRY STRAINS.

One of your correspondents last week, writing on this subject, asks, Is not white a sign in most animals of impurity of strain or cross? I believe it is a sign of deterioration in physical power, and I see no reason why it should not be so as to colour and other hereditary dispositions. This, even established as a fact, would not affect my statement quoted by your correspondent—namely, that white and black, and white and yellow, seem to be interchangeable colours, whilst red remains unchanged.

The results of your correspondent's attempt in mating Cochin hens of a uniform sandy buff colour for one season with a

White Dorking cock, and in the following season with a Grey Dorking cock, go far to prove my statement. The result of the first year's breeding was to produce from the yellow hens by a white cock bird exactly what I stated—namely, white for yellow. The result of the second year would seem to show that yellow and black stand in the same position. At all events the white neck, hackle, back, saddle, and wing of the Grey Dorking answered the condition of a change from yellow to white in the progeny of the Buff Cochin hens; for sandy buff is to all intents and purposes a yellow. That black and white are interchangeable is, beyond the result in breeding Pile Game, widened by the fact that in mating Golden-spangled with White Polish fowls, to produce the Chamois Polish, the black spangle becomes white.

The case of interchange between yellow and white is not so clearly shown as the above, and that between yellow and black needs more experiment before it can be asserted. The matter, however, is of very great interest, and by experiment it may lead to the establishment of certain laws connected with colours in breeding, of which we are at present ignorant.

By pursuing this inquiry, the breeding of fancy poultry will add to its importance in combining the science of natural laws with amusement; and the question, which in a former number I mooted with regard to the external influences of colour, will, if established by experiments, be one of very many proofs that the Holy Scriptures are veritable records, and the truthful exponents of everyday life if we will but read them practically, and not regard them afar off as tables of stone on a cloud-capped mountain.—Egomet.

COMMITTEEMEN EXHIBITING.

I refrained from replying to "Egomet's" letter in the Journal of the 11th November, as before doing so I was desirous of seeing "Justice's" answer to my question. Since then, business and other engagements, and a sick house, have prevented my attending to the subject, and on returning to it I find I have a deal of leeway to make up. I can assure "Egomet" I did not consider his first communication as "meddlesome." I think that when any question is opened up in the columns of a public journal it becomes at once public property, and it is competent for anyone to express an opinion on the matter.

Reverting to my article of November 4th, I really am at a loss to discover what there is in it to justify "Egomet" in drawing the "*quid pro quo*" inference. To a committee such as I have in my eye, anything like a money value, "*quid pro quo*," is the very last thing which would enter their minds. I must say I think the deduction hardly a fair one. I admit the "confusion of pronouns," but if "Egomet" will refer to the article again I will try to make it clear. I meant that it—*i.e.*, the offer of a local cup—affords him—*i.e.*, the local exhibitor—an opportunity of competing among his fellows for a a trophy which the foreign exhibitor cannot touch; it—*i.e.*, the local cup, is far beyond his (the foreign exhibitor's) reach, by being made local. The "contingency" I supposed was that of a local man winning both cups; and what I meant by its frequent recurrence defeating the object of a committee in offering a local cup was just this, that it would show there was no necessity for offering any additional inducement to the local man, since his success would demonstrate his capability to compete successfully against all comers, and in such a case, were I on the committee, I should then move the withdrawal of the local cup as having accomplished its mission. I hope I make myself sufficiently understood. I am reasoning on the supposition that if the All-England cup be considered beyond the reach of the local man, then let him have his local cup; but, if the result of a show proves that the local man can win the All-England prize, then remove the local cup as having no honour attached to it beyond its value as old silver.

On the 18th November "Justice" replies for himself. He says that the evil consequent upon committeemen exhibiting at shows under their own management "simply consists in the amount of dissatisfaction and distrust it engenders in the minds of absent exhibitors." I anticipated his reply. I am sorry if "Justice" has experienced satisfactory grounds for such "distrust and dissatisfaction." If so, let him for the future avoid the society where he suspects foul play. But I am afraid he is of a rather suspicious disposition, and I think he cannot censure me for speaking so plainly, when he advances such an unheard-of idea as that exhibitors should be allowed to witness the judging where practicable! His previous statement that committeemen should not be allowed to exhibit, of course implied a guilty complicity on the part of the judges, without whose connivance no fraud could be perpetrated, and I am not now surprised at his openly stating that the judges themselves should be under the eye of the exhibitor. He appears to have been at a show where such an insult was offered to a judge, and where a man was found to tolerate such espionage. I do not envy the committee who allowed such a proceeding; they did not know their business, which would perhaps account for their appointing the individual to handle the birds, who took "valuable birds by the leg, the wing, and not unfrequently by the neck, and handed to the judge for examination." What was the judge about, what were the lynx-eyed exhibitors about, that they did not take him by the neck?

I must either be very incapable of expressing my meaning intelligibly, or "Justice" reads with strange mental obliquity, when he interprets what I say about "measuring with their own eyes," &c., to mean anything so absurd as his construction of it. I agree with him; such Quixotic conduct, as he describes, on the part of any exhibitor would indicate "sheer madness." "Anything more preposterous than such an idea" it is difficult to imagine. I never contemplated such a thing.

"Justice" further says that he cannot agree with me "that local prizes are given on the assumption that the local man has but small chance against the outside competitor." That is the only ground on which I justify the offering of a local cup. Once let the local man prove his ability to enter the All-England arena, and then away with the local prize, prescribed as it is in its orbit, and consequent value as a prize. I wish "Justice" to understand that I know nothing of Long Sutton or its shows, or what may have transpired there. I am only trying to show that the offering of a local prize ought not to affect the interests of outside exhibitors in the slightest degree, and I am also trying to show that when such local prize has accomplished the only object which would justify its institution, it should then be withdrawn, being barren of honour, as the greater would include the less.

Then "An Old Committeeman" takes up the cudgels, followed by "Claude," who arrives at conclusions quite foreign to the spirit of my communication. The commercial element he introduces has no home with my "carpet knights," and "Claude" ought not to impute such mercenary motives to exhibiting committeemen—it is not charitable; but I can assure him that, as an almost universal rule, shares in a poultry show would be quoted in the market very much below par. The rest of his letter I am disposed to pass by: the pictures are so dismal. But I cannot see what "conscientious" scruples there can be to prevent a person undertaking the office of committeeman for no other reason than that the show does not pay expenses, for that is all that "Claude's" statement amounts to. "All exhibitors have been pleased," and therefore there must have been fair play, and no distrust or dissatisfaction. But their pleasure is damped by having to subscribe to make up a deficit. Permit me to say that it is no damper to a right-thinking body of men. They enter into the work *con amore*, and are quite prepared to meet the exigencies of the case, and the fact of the recipient of this deficit being a stingy committeeman does not do away with the deficit which would exist whether he were on the committee or not. The mistake is in having such a stingy man in office. To assume, also, that this unfortunate man's prize money is the total deficiency of the society shows a bad state of things, for no show ought to issue its schedule till the amount of prize money is guaranteed or in hand. Pay all prizes first, and promptly, too, and then, in case of a deficit, let all fare alike, and the stingy character will have to pay his share, or find his level in a society more congenial to his money-grubbing propensities. I hope the poor man who spent a sixth part of his yearly income when he could not afford it has no wife and children. Let me advise that he be closely watched by his friends.

"An Old Committeeman" is, as "Egomet" says, "so temperate and persuasive;" I have to thank him for a line of argument I could not have followed out so ably as he. His remarks, December 2nd, involve very weighty considerations, for, as I have mentioned before, a corrupt committee implies a corrupt judge. Can such things be? I read an *exposé* some time back, in which two new hats and a sovereign were placed in the scale as the exhibitor's estimate of a judge's integrity, and in that case the bribe

"Flew up and kicked the beam."

I cannot believe in corrupt judges as a class, and without them we cannot have corrupt committees, and I think that curtailing the action of a committee on grounds that impeach alike their

integrity and that of the judge, is indeed treading on very delicate ground. To prohibit committeemen exhibiting would not effect a cure, for the corrupt judge would still be accessible from without, and a corrupt committeeman would soon find means to evade the *bonâ-fide* property clause found in most schedules, and secure to himself, with the connivance of another unprincipled exhibitor, the coveted prize. "Where there's a will there's a way" in knavery as in honest dealing, and while I fully concur with "EGOMET" in the axiom that prevention is better than detection, I ask him, as one who, I am fully persuaded, has the best interests of exhibitions at heart, whether it is well to encourage that spirit of distrust and dissatisfaction only too often the offspring of groundless suspicion, and so hurt the feelings of honourable men, whose conduct of the shows they manage is such as ought to place them above suspicion? Shows so conducted are sure to occupy the most prominent position in the estimation of all right-thinking men, and while every precaution ought to be taken to ensure fair play, and so merit the confidence of the exhibiting community, I should be much grieved if malpractices became so general as to render imperative a universal vote of want of confidence in the executive of our shows.

If I am not trespassing on space too much (and let me beg an extra line or two as I have been silent so long), I will just explain to "EGOMET" and "JUSTICE" the working of a very large show—the largest provincial show of its kind in England—with which I am connected. Our committee, I am happy to say, are all gentlemen, and nearly all, if not all of them, are exhibitors in every show we manage. When our entries are closed we send out a numbered label for each entry, which is attached to the pen, cage, or animal, as the case may be. These are subsequently changed by the secretary, who alone possesses the key to the whole. This duty generally occupies him the entire night, from the close of the receiving day till the next morning, and unless any of the committee are very early astir, and make it their business to enter the show room (which they are expected for honesty's sake not to do), not one of them knows his new numbers, so that collusion with the judges is next to an impossibility. Next, we have judges of known repute, who are shut into the room by daylight on the judging day, and allowed to communicate with no one till their duties are over, when they deliver their verdict to the committee and such exhibitors as may happen to be in or near the building, and who are invited to hear the awards announced. Last year the result of the verdict was that our All-England cup and our local cup were both won (for the first time) by one of the committee, who at once received the congratulations of several non-successful exhibitors present, who year after year have come hundreds of miles to compete for our prizes, and to whom the working of our show is as familiar in its details as to ourselves. Our patrons are legion, and I do not believe there is one of them who would wish to debar a single committeeman from exhibiting, or one whose confidence in us is not unbounded.—ALIQUIS.

THERE can be no doubt that poultry shows are now more numerous and successful than they ever were before, and to keep them in this satisfactory state all unfair acts of exhibitors, secretaries, and committees, should be properly exposed; and I quite agree with Mr. Wright, that an organisation or "court of appeal" should be formed, where we could discuss any subject connected with poultry. I think we should likewise take notice of unsatisfactory awards made by the judges, for many prizes recently given to exhibitors have been far rom satisfactory to the great body of those who support our shows, and I hope to see this subject thoroughly ventilated in your columns. I feel certain if something of this kind existed, we should not find the uneasiness now felt by some of your correspondents at secretaries and committees exhibiting at their own shows.

The last-named subject appears to have created a vast amount of dissatisfaction amongst a few gentlemen. Why, I am at a loss to conceive. I happen to be acquainted with a large number of breeders and exhibitors of poultry and Pigeons; some are secretaries, others are committeemen, while others are only exhibitors, but in every case where the subject has been mooted, one and all considered that secretaries and committeemen have a perfect right to compete for prizes at their own shows. The prizes and expenses are guaranteed by the committee, should the undertaking prove a failure they have to make good the deficit. The prizes are open to all, and subject to the same rules, then why should not committeemen compete too? "Oh!" says one directly, "he then becomes a hireling." Is it possible for a man to become a "hireling" on his assisting to guarantee certain sums of money for an open competition, the birds to be judged by an experienced and well-known, but an entirely disinterested gentleman, who knows not to whom the birds belong? He may win nothing, and at the close have to pay a sum of £20 towards the expenses, just as one secretary I knew had to do. One might say with equal justice that the whole body of committeemen become "hirelings," because they are paid money in the form of entry fees by competitors who wish to be allowed to compete for the prizes, and, to carry the idea a little further, that a successful exhibitor also becomes a "hireling" of the committeemen, on his receiving a prize in an open and equitable competition.

On these conditions it seems to me unfair and unjust to brand a secretary or committeeman as a "hireling," because he chooses to compete with others at his own show. If otherwise, then I for one must say good-bye to our poultry shows, for depend upon it they will soon cease on taking away their main support. Another talks of "dissatisfaction." Well, everyone knows about that, and I think all will admit there has hardly ever been a show held where it was not to be found. Some exhibitors are disappointed at their not getting a prize, some justly, others because they can never see their own faults. We shall always find this to be the case where a number of people compete for a few prizes.

I was much pleased with some of the remarks made by "CLAUDE," the more so because he unintentionally hit the right nail on the head. His sentence runs as follows—"We look upon these shows as a means to encourage us to improve the breed of our stock, and to enable those who take an interest in this, for the love of it, to compete." There he is right, "to improve the breed, and for the love of it to compete."—AN AMATEUR.

I THINK if "EGOMET" and "CLAUDE," considered the matter even for an instant, they could not arrive at their present conclusion with reference to committeemen exhibiting at their own shows. As has been often asserted in "our Journal," poultry shows must be organised by those who are themselves fanciers, and who must make every effort, even at great personal inconvenience, for the advancement of the exhibition, otherwise almost invariably it will be a failure. Now, it is in many instances the case (I am a committeeman, and it is in mine), that the show of which an exhibitor is a committeeman is the only one which he has an opportunity of attending, or at which he has an opportunity of seeing his birds compete with others. If in his capacity of unpaid official he were precluded from exhibiting he would have but two alternatives—namely, either to lose in a great measure the pleasure he has in producing good birds, or to resign his position as committeeman; and if every local exhibitor resigned his place on the committee, perhaps "EGOMET" or "CLAUDE" could suggest as to how the show would be sustained. I really must say the remarks of many writers of late cast a very unfair slur on the character of committees in general.

The basis of the objection to officials exhibiting must be, that they have opportunities of communicating with the judges, which outsiders have not. To this accusation, for I must call it one, my only reply can be that any one, no matter who he may be, who takes advantage of an unscrupulous judge by endeavouring to obtain prizes to which he is not justly entitled is not fit to remain in the society of honourable men. I am sure that the discovery of any unfair dealing on the part of any member of a society would result in his ignominious expulsion. The judges are also pointed at; for if they are strictly upright and honourable men, which I believe the leading ones of the present day to be, they will not lend an ear to the nefarious proposals of any exhibitor, but of course if they think fit they are able to defend themselves.

I hope that the majority of exhibitors will now see the impossibility of organising a show without the personal co-operation of fanciers, and the absurdity of denying those amateurs who undertake the arduous duty of committeemen the gratification of seeing their birds join in an honourable competition, and on equal terms with other exhibitors.—AN IRISH COMMITTEEMAN.

WHITEHAVEN POULTRY SHOW.—This annual show will take place on the 28th, 29th, and 30th inst., the first day being private and for judging, the second and third for public exhibition. The prizes offered almost in every class consist of five and three-guinea cups, with money prizes of £2, £1, 10s.,

&c. The Judges already appointed are, for poultry, Messrs. Hewitt and Teebsy. A Judge for Pigeons will be appointed. The entries close on December 16th. Further particulars are in our advertising columns.

DORKING POULTRY SHOW.

Most poultry amateurs would naturally anticipate something unusually good from a locality so noted in the poultry world as Dorking, and those who were so fortunate as to be able to visit the Show held on the 9th and 10th inst. would find their anticipations realised. The general classes were well filled with some of the finest specimens in the kingdom. The managing Committee have evidently an eye to utility, for except Coloured *Dorkings*, Blue Speckled Dorkings, and White ones, the only other classes in the Show were *Turkeys*, *Geese*, and Rouen and Aylesbury *Ducks*. The latter classes, too, had many most excellent birds in them, perfect in plumage, and of capital size. Dorkings, however, are naturally the main feature of the Dorking Show, and it would be difficult to imagine better-filled classes than those purposely restricted to the neighbourhood, and those open to every one who chose to enter for competition.

The first class for old birds was open to all England, and the plate prize was secured by Dr. Campbell, very closely pressed, however, by the second-prize pen belonging to Mr. Henry Humphrey, of Ashington, Sussex. The second class (also open) was for a cockerel and two pullets, but here a truly remarkable pen of chickens belonging to the district, the property of Messrs. Ivery, kept the plate in the locality; Mr. Parlett taking the second, and Dr. Campbell the third prize. In the open class for Coloured Dorking cockerels there was much competition, the Rev. E. Bartrum, Mr. C. Havers, and Mr. M. Putney taking the three prizes. For the local classes it would be invidious to say anything farther than that all the birds were excellent, and the colour of all was unusually good, whilst the condition was absolutely faultless. A reference to the appended prize list will prove that the prizes were unusually broadcast. The Blue Speckled Dorkings were not nearly so commendable classes as the Whites, the latter being much better than those entered at most poultry shows. We cannot forbear a passing mention of Mr. Joseph Clift's pair of old Dorking hens, and also Mr. Ivery's splendid pair of pullets of the same variety. As the Assembly Rooms were not sufficiently capacious to hold the whole of the entries, the Turkeys, Geese, and Ducks were exhibited in two very large coach houses. Mr. Billett, of Southampton, supplied the exhibition pens, which are well calculated to show off all descriptions of poultry to great advantage, being somewhat larger than most pens of this description.

Dorkings (Coloured).—1, Dr. Campbell, Brentwood. 2, H. Humphrey. 3, H. Lingwood. *c*, Major Calvert. *Chickens.*—1, J. Ivery & Son, Dorking. 2, F. Parlett. 3, Dr. Campbell. *hc*, Major Calvert; A. & E. Stanford. *c*, J. Clift. *Cockerel*—1, Rev. E. Bartrum, Great Berkhampstead. 2, C. Havers, Ingatestone. 3, M. Putney. *hc*, Dr. Campbell; Lord Turnour, Shillinglee Park. *c*, W. Fell; J. Ivery & Son.

White Dorking Cock.—1, Lady Legge. 2, W. Attlee. *c*, Mrs. Matheson.

LOCAL CLASSES.

Dorking (Coloured).—1, M. Putney. 2, J. Ivery & Son. 3, H. Lainson. 4, E. T. Bennet. *Chickens.*—1, G. Ellis. 2, J. Clift. 3, J. Ivery & Son, Dorking. 4, Major Calvert. *hc*, J. Clift; J. Ivery & Son; M. Putney. *c*, E. T. Bennett; G. Ellis. *Hens.*—1, J. Clift. 2, M. Putney. *hc*, E. T. Bennett; Major Calvert; W. Fell; J. Ivery & Son. *c*, D. B. Green. *Pullets.*—1, J. Ivery & Son. 2, W. Fell. *hc*, E. T. Bennett; M. Putney. *Cock.*—1, J. Ivery & Son. 2 and *c*, E. T. Bennett. *Cockerel.*—1, J. Wood. 2, M. Putney. *hc*, J. Ivery & Son. *c*, W. Fell; J. Ivery & Son.

Dorking (Blue Speckled).—1, W. Griffin. *Chickens.*—1, W. Griffin. 2, J. Wood; 3, J. Carpenter. *Cock.*—1, E. Neal. *Hens or Pullets.*—1, Major Calvert.

Dorking (White).—1, W. Attlee. 2, G. Cubitt. 3, J. Bargman. *hc*, W. Shearburn. *Chickens.*—1, Mrs. Burt. 2 and *hc*, J. Attlee. 3, W. Shearburn. *Hens or Pullets.*—1, W. Attlee. *hc*, W. Attlee; T. Sherlock.

Ducks (White Aylesbury).—1, J. B. Nichols. 2, H. Lainson. 3, E. T. Bennet. *hc*, J. Wood.

Ducks (Any other breed).—1, A. Belcher. 2, J. Ivery & Son. 3, Mrs. Norris. *hc*, G. Cubitt, M.P.

Geese.—1, Mrs. Norris. 2, W. Messenger. *c*, J. Rose. *Goslings.*—1, W. Messenger. 2, W. Attlee. *hc*, H. Wise.

Turkeys.—1, Sir R. A. Glass. 2, W. Messenger. *c*, H. Lainson.

The Judge was Edward Hewitt, Esq., of Eden Cottage, Sparkbrook, near Birmingham.

LONGTOWN POULTRY SHOW.

This Show, though small, was very well managed, and the specimens well attended to. The quality of the birds was very good in all departments. The first-prize single *Game* cockerel was a neatly-moulded bird, though a little out of condition, and the second and third-prize birds were also fair specimens. The adult Game cocks were excellent in colour, and good in hand, but the next class of chickens was not so good. The first-prize Duckwing cock was of striking quality in colour and marking. Of *Hamburghs*, only the winners were noteworthy; but the *Dorkings* and *Spanish* were good and well shown. In the "Variety" class excellent White Bantams were first, with Silver *Polands* second. Some of the Game *Bantams* were very neat and game-looking, though some of the others were too long in the wing. The *Geese* were very large, and the first-prize Toulouse of capital colour. Dorkings and Rouen Ducks won respectively in the selling class. In the class for *Bantams* of any variety except Game, Blacks of the highest quality were first, with neat Booted Whites second.

Among the *Pigeons*, Carriers were first, Pouters second, and Fantails third and highly commended. The *Canaries* were mostly of the common straight varieties, but were very good.

Game.—1, W. Graham, Cliff. 2, J. Gaddess, Harker. *hc*, Joseph Brough, Carlisle. *Chickens.*—1, John Brough, Carlisle. 2, R. Fawkes, Crossings. *c*, J. Pearson, Bradford; J. Barrow, jun., Kendal. *Cock.*—1, — Ackroyd, Bradford. 2, J. Gaddess. 3, J. Barrow, Kendal. *hc*, John Brough. *c*, J. H. Dawes; R. Jackson, Carlisle; Joseph Brough.

Game (Duckwings, &c.).—1, T. Davidson, Longtown. 2, John Brough. *hc*, W. Walton, Cocklake.

Hamburghs (Golden-spangled).—1, S. & R. Ashton, Roe Cross, Mottram. 2 and *hc*, R. Rickson, Selkirk.

Hamburghs (Golden-pencilled).—1, Mrs. Johnson. 2, E. Grieve, Chapel Hill, Canonbie. *hc*, E. Greave; H. Pickles, jun., Earby, Skipton. *c*, J. Armstrong, Longtown; T. Kean, Hollows; J. Nicholson, jun., Carlisle.

Hamburghs (Silver-spangled).—1, W. Bowe, Carlisle. 2, J. Pearson, Allerton. *hc*, H. Pickles, jun. *c*, W. Crosthwaite, Stanwix.

Hamburghs (Silver-pencilled).—1, J. Pearson. 2, H. Pickles, jun.

Dorkings.—1, H. Pickles, jun. 2 and *hc*, R. Reed, Moat.

Spanish (Black).—1, H. Wilkinson, Earby. 2, R. Reed.

Any other Variety.—1, S. & R. Ashton (White Bantams). 2, J. S. Watson, Earby, Skipton. *hc*, J. B. Story, jun., Milnhead, Dumfries (Partridge Cochins). *c*, T. McKie, Esk Bank (Scotch Greys).

Game Bantams (Any colour).—1, R. Little, Dickstree. 2, G. Hall, Kendal. *c*, T. Taylor, Kendal; Joseph Brough.

Geese.—1, D. Hardie, Sorbie. 2, Mrs. McBurnie, Fauld Mill. *hc*, R. Reed.

Ducks (Aylesbury).—2, D. Hardie.

Ducks (Rouen).—1, D. Hardie. 2, T. Taylor.

Selling Class.—1, R. Reed (Dorkings). 2, D. Hardie (Rouen Ducks). *vhc*, J. B. Story. *hc*, Mrs. Johnston (Golden-pencilled); S. & R. Ashton. *c*, T. Taylor (Ducks); H. Wilkinson (Buff Cochins).

Sweepstakes for Hens.—*Dorkings.*—1, M. Taylor, Penrith. *Hamburghs.*—1, J. Sibson, Carlisle. 2, H. Pickles, jun. *hc*, J. Armstrong. *Game.*—1, Bellingham & Gill, Burnley. 2, R. Irving, Dickstree. *hc*, E. I. Musgrave, Longtown. *Cochins.*—1, J. B. Story. 2, M. Taylor, jun., Penrith.

Bantams (Any variety except Game).—1, W. H. Tomlinson, Newark-on-Trent (Black). 2, J. B. Story (White). *hc*, H. Pickles, jun. (Black).

Pigeons (Any variety).—1, J. Guthrie, Hexham (Carriers). 2, J. & W. Towerson, Egremont. 3, W. H. Tomlinson. *hc*, W. H. Tomlinson (White Fantails); F. D. Graham, Birkenhead. *c*, J. Sibson (Dun Carriers); J. and W. Towerson; H. Sawyers, Carlisle (Yellow Turbits).

Canaries Any variety).—*Cock.*—1 and 2, W. Hutton, Purdhams Crook. *hc*, Miss E. Jackson, Longtown; J. H. Jackson, Longtown; J. Chambers, Longtown. *c*, T. Davidson, Longtown.

The Judge was Mr. Hutton, of Pudsey.

YORK POULTRY SHOW.

This was held on the 7th, 8th, and 9th inst., in conjunction with the Christmas cattle show.

The entries of Poultry were 334; of Pigeons, 157; of Rabbits 69; total 560; being an increase of 145 pens over last year. The longest ears of the Rabbits measured 22½ inches; and the heaviest weighed 14¼ lbs. The following is a list of the awards:—

Dorking (Any colour).—1, J. White, Warlaby. 2, W. Bearpark, Ainderby Steeple, Northallerton. *Chickens.*—1, J. White. 2, T. E. Kell, Wetherby.

Spanish.—1, H. Beldon, Goitstock, Bingley. 2, E. Brown, Sheffield. *Chickens.*—1, H. Beldon. 2, E. Brown.

Cochin-China (Yellow or Buff).—1 and Cup, C. Sidgwick, Ryddlesden Hall, Keighley. 2, H. Steward, Bishopthorpe.

Cochin-China (Any other colour).—1, C. Sidgwick. 2, J. Bell, Thirsk. *Chickens.*—1, C. Sidgwick. 2, H. W. Illingworth, Idle.

Brahma Pootra.—1, W. Whiteley, Clough Lodge, Sheffield. 2, G. Palfreyman, jun., Heeley, Sheffield.

Game (Black-breasted or other Reds).—1, H. M. Julian, Hull. 2, T. Hawks, Hunsingore, Wetherby.

Game (Duckwings).—1, E. Winwood, Worcester. 2, H. M. Julian.

Game (Any other variety).—1, G. Pounder, Kirby Moorside. 2, E. Winwood. *Chickens.*—1, J. H. Smith, Skelton. 2, T. Dyson, Halifax.

Hamburghs (Golden-pencilled).—1, J. Walker, Birstwith, Ripley. 2 and 3, H. Beldon.

Hamburghs (silver-pencilled).—1, H. Smith, Morton Banks, Keighley. 2, H. Pickles, jun., Earby. 3, H. Beldon.

Hamburghs (Golden-spangled).—1, J. Rellinson, Lindley, Otley. 2, W. Driver, Keighley. 3, T. Dean, Keighley.

Hamburghs (Silver-spangled).—1 and 3, H. Beldon. 2, R. Pickles, jun.

Polish.—1, Mrs. Proctor, Hull. 2, H. Beldon.

Game Bantams.—1, Bellingham & Gill, Burnley. 2 and 3, W. Hodgson, Darlington.

Bantams (Laced).—1, H. Beldon. 2, F. Powell, Knaresborough.

Bantams (Any other colour).—1, G. Atkinson, Darlington. 2, W. Hodgson.

Any other Variety.—1, C. Sidgwick. 2, R. Loft, Woodmansey, Beverley.

Turkeys.—1, F. C. Matthews, Driffield. 2, J. B. Braithwaite, North Otterington. *Poults.*—1, F. C. Matthews. 2, E. Barker, Stokesley.

Geese.—1, G. Hustler, Stillingfleet. 2, Lord Wenlock, Escrick Park.

Ducks (Aylesbury).—1, J. Story, Warter, Pocklington. 2, W. Stonehouse, Whitby.

Ducks (Rouen).—1 and 2, Mrs. Stamper, Highfield House, Oswaldkirk.

Ducks (Any variety).—1 and 2, C. N. Baker, Chelsea.

Selling Class.—1, G. Calvert, Darlington. 2, H. Beldon. 3, J. Hearfield, Darlington.

PIGEONS.

Carriers.—*Cock.*—1, W. R. & H. O. Blankinsop, Newcastle-on-Tyne. 2, E. Horner, Harewood, Leeds. *Hen.*—1 and Cup, J. Thompson, Bingley. 2, F. J. Leach, Middlesbrough.

POUTER (Any colour).—*Cock.*—1, E. Horner. 2, J. Hawley. *Hen.*—1 and 2, E. Horner.

TUMBLERS (Almond).—1 and 2, J. Fielding, jun., Rochdale.

TUMBLERS (Short-faced).—1, R. Minnitt, jun., Healey, Rochdale. 2, J. Fielding, jun.

FANTAILS.—1, T. Rule, Durham. 2, D. McCollin, Hull.

TRUMPETERS.—1, J. Firth, jun., Dewsbury. 2, S. Robson, Brotherton, Ferrybridge.

BARBS.—1, 2, and piece of plate, J. Gell, York.

JACOBINS.—1, E. Horner. 2, J. Thompson.

TURBITS.—1, G. Fletcher, Acomb Landing. 2, H. Whittaker, Heslington.

OWLS.—1, J. Fielding, jun. 2, F. Key, Beverley.

NUNS.—1 and 2, W. Croft, Killinghall, Ripley.

ANY OTHER NEW OR DISTINCT VARIETY.—1, J. Fielding, jun. 2, E. Horner.

SELLING CLASS.—1, J. Thompson. 2, E. Horner. 3, W. Campey, Beverley.

RABBITS.—*Lop-eared.*—Cup for best buck or doe, bred in 1869, T. Taylor, York; also special prize for longest-eared. *Lop-eared buck or doe, self-coloured* (All properties).—1, C. Gravil, jun., Therne. 2, C. King, St. John's Wood, London. *Lop-eared buck or doe, Yellow and White, or Tortoiseshell* (All properties).—1, A. H. Easten, Hull. 2, B. Hudson, Hull. *Lop-eared buck or doe, Black and White, or Grey and White* (All properties). 1, A. H. Easten. 2, J. Hume, York. *Heaviest.*—1, J. Pearson, York. 2, A. H. Easten. *Himalayan.*—1, J. Ranstreu, Haslingden. 2, J. Butterworth, Rochdale. *Dutch.*—1, T. W. Harrison, York. 2, S. G. Hudson, Hull. *Any other Variety.*—1, A. H. Easten. 2, P. F. Martin, Rawcliffe. *Selling Class.*—1, S. Hall, York. 2, C. King.

Judges for *Poultry:* Mr. R. Teebay, Fulwood, Preston; for *Pigeons:* Mr. W. Massey, Spalding, and Mr. H. Brown, Walkeley, Sheffield; for *Rabbits:* Mr. Millington, of York.

BRADFORD POULTRY SHOW.

THE following is the prize list of this Show, held on the 9th, 10th, and 11th inst:—

SPANISH.—Cup, C. W. Brierley, Haywood, Manchester. 2, H. Wilkinson, Earby, near Skipton. Extra 2, H. Beldon, Goitstock, near Bingley. *hc*, W. R. Bull, Newport Pagnell; J. F. Dixon, Cotgrove, Nottingham; F. & C. Haworth, Haslingden; Burch & Boulter, Sheffield. *c*, J. Thresh, Bradford; F. & C. Haworth.

DORKINGS.—1, H. Crossley, Bleomfield, Halifax. 2, W. Harvey, Sheffield. 3, W. H. King, Rochdale. *hc*, R. W. Richardson, Beverley; E. Leech, Rochdale; J. Martin, Claines, Worcester. *c*, Hon. H. W. Fitzwilliam, Wentwerth Woodhouse.

GAME (Black-breasted Red).—1, W. Beyes, Beverley. 2, E. Aykroyd, Bradford. 3, W. Spencer, Haworth.

GAME (Brown-breasted Red).—Cup, E. Aykroyd. 2, T. Bottomley, Shelf, Halifax. 3, W. Johnson, Idle.

GAME (Any other variety).—1, J. Fletcher, Stoneclough, Manchester (Duckwing). 2, J. Sunderland, Halifax (Pile). 3, C. Chaloner, Whitwell, Chesterfield. *hc*, E. Nayler, Heckmondwike (Duckwing). *c*, W. J. Cope, Barnsley (Duckwing).

BRAHMAS (Dark).—1, Hon. Mrs. B. Hamilton, Ridgweed, Woburn. 2, F. Powell, Knaresborough. 3, E. Leech, Rochdale. *hc*, W. Harvey; H. Lacy, Hebden Bridge; F. & C. Haworth, Newfield. *c*, H. Lingwood, Needham Market.

BRAHMAS (Light).—1, H. Lacy. 2, J. Pares, Postford, Guildford. 3 and *c*, W. Whiteley, Sheffield. *hc*, F. Crook, Forest Hill.

COCHIN-CHINA (Cinnamon and Buff).—Cup, W. A. Taylor, Manchester. 2, J. Cattell, Birmingham. 3, H. Mapplebeck, Moseley, Birmingham. *hc*, W. Harvey; Mrs. Allsepp; J. Lee, Middleton. *c*, Bowman & Fearon, Whitehaven; R. White.

COCHIN-CHINA (Any other variety).—1, W. A. Taylor. 2, T. Stretch, Ormskirk (Partridge). 3, R. White (Partridge). *hc*, H. Lingwood (Partridge); Bowman & Fearon.

HAMBURGHS (Golden-pencilled).—Cup, J. Smith, Goitstock, Bingley. 2, H. Beldon, Goitstock, Bingley. 3, J. Walker, Keadsl. *hc*, J. Laming, Cowburn, Spalding; T. Wrigley, jun., Middleton.

HAMBURGHS (Silver-pencilled).—1, J. Walker, Birtswith, Ripley. 2, Mrs. Allsopp. 3, Duke of Sutherland, Trentham, Steke-en-Trent. *hc*, R. Longbottom. *c*, W. Park.

HAMBURGHS (Gold-spangled).—1, T. Dean. 2, W. Driver, Keighley. 3, W. A. Hyde, Ashton-under-Lyne. *hc*, J. Chadderton, Hollingweed; H. Pickles, jun, Earby, Skipton; J. Rollinson, Lindley. *c*, J. Chadderton; J. Ogden, Hellingweed.

HAMBURGHS (Silver-spangled).—Cup and 2, Ashton & Beeth, Mottram. 3, J. Laming. *hc*, W. A. Taylor; J. Fielding, Newchurch, Manchester.

HAMBURGHS (Black).—1, C. Sidgwick, Ryddlesden, Keighley. 2, S. Butterfield, Keighley. 3, T. Walker, jun., Denton. *hc*, J. Smith, Keighley; D. Clayton, Bradford; J. Holt, Middleton. *c*, J. Laming.

POLANDS (Any variety).—1 and Oil Painting, W. Harvey. 2, H. Beldon. 3, W. Gamon, Chester. *hc*, T. Dean; W. Patrick, West Winch (Gold).

ANY OTHER DISTINCT BREED.—1, W. R. Park (Crève-Cœurs). 2, R. Loft, Woodmansey (Sultans). 3, Hon. C. W. Fitzwilliam, Wentwerth Woodhouse (La Flèche). *hc*, W. Harvey (French); L. Biney, Manchester; J. J. Waller, Kendal (Malays); S. H. Stott, Rochdale (Houdans); W. H. Towle, Southport (Houdans).

GAME BANTAMS (Black Reds).—Cup, G. Maples, jun., Wavertree. 2, J. H. Wilson, St. Bees. 3, G. Noble, Staincliffe. *hc*, J. Holland, Northwich; J. R. Robinson, Sunderland.

GAME BANTAMS (Any other variety).—1 and Painting, J. Stabler, Great Driffield (Piles). 2, T. Whittaker, Melton Mewbray (Piles). 3, J. Cresland, jun., Wakefield (Duckwings). *hc*, W. F. Entwisle, Westfield (Black Game); J. Cresland, jun. (Brown Reds); E. & J. Lund, Shipley (Duckwing); W. Parker, Clay Cross (Piles); A. Ramsden, Swamp, Queensbury; W. Greaves, Bradford (Duckwing); Bellingham & Gill, Burnley (Piles); G. Smith; J. Frith.

BANTAMS (Any other variety).—1, J. Walker (Black). 2, Miss A. Hodson, Bridgewater (Sebright). 3, Mrs. Woodcock, Rearsby, Leicester (Japanese). *hc*, W. A. Taylor (Black); W. H. Robinson (Black); W. Cannao, Bradford (Black); J. H. Dawes (Japanese); W. J. Cope (Pekin).

SELLING CLASS.—1, J. Newton, Silsden, near Leeds (Spanish). 2, W. A. Burnell, Southwell, Notts (Buff Cochins). 3, Mrs. J. Cross (Crève-Cœurs). 4, R. Loft (Sultans). 5, C. W. Brierley. *hc*, T. Dean (Polands); J. Bewker, Keighley (Poland); S. Bentham, Bradford (Game); J. Smith (Game); Rev. P. W. Storey, Daventry (Japanese Bantams); W. A. Burnell (Buff Cochins); W. Johnson, Idle, near Leeds (Game); J. Powell, Bradford (Spanish); C. Travice, Thorland, near Sheffield (Game and Cochins); E. Leech; J. Sugden, Thornton, near Bradford (Hamburghs); H. Wilkinson (Brahmas); J. White; C. W. Brierley; J. S. Waller; J. W. Wilkinson; Gunson & Jefferson, Whitehaven; T. Suddick, Bradford (Game); W. J. Cope (Game). *c*, J. T. Beeth (Spanish); W. Charter, Great Driffield; J. Berry, Silsden (Spanish); J. Hodgson, Bradford (Game); J. W. Wilkinson (Game); J. Spencer, Clayton, near Bradford (Game); H. Jowett, Idle, near Leeds (Game).

SINGLE COCKS.—*Game* (Any colour).—Cup, C. W. Brierley. 2, W. H. Robinson, Keighley. 3, N. Grimshaw. *hc*, J. Fletcher (Black Red); Capt. G. Price; J. H. Wilson. *Bantam* (Any variety).—Cup, J. W. Morris. 2, G. Hall, Kendal (Game). 3, Bowman & Fearon. *Hamburgh* (Any variety).—1, W. A. Hyde (Golden-spangled). 2, S. Lord, Rochdale. 3, T. Kinder, Mickelthwaite, near Bingley (Golden-pencilled). *hc*, W. Clayton (Golden-pencilled). *Cochin* (Any colour).—1, W. A. Taylor. 2, Mrs. Allsopp. 3, J. Cattell. *hc*, J. K. Fowler, Aylesbury (Partridge).

GAME HEN (Any colour).—Cup, E. Ackroyd. 2, C. W. Brierley. 3, J. Fletcher (Black Red). 4, C. Chaloner. *hc*, J. Fletcher (Black Red); J. R. Robinson; J. Walker; R. Payne, Brierfield, Burnley; W. Whewell, Redcliffe, near Manchester. *c*, W. Whewell.

DUCKS (Aylesbury).—1 and 3, H. Jones, Dinton, Ayleshury. 2, W. Stonehouse. *hc*, E. Leech; T. Wilson.

DUCKS (Rouen).—1, A. Woods, Sefton, Liverpool. 2, W. Gamon. 3, E. Leech. *hc*, J. K. Fowler; A. & J. Trickett, Waterfont, near Manchester.

DUCKS (Any other variety).—1, C. W. Brierley. 2, S. Burn (Mandarin). 3, C. & J. Trickett. *hc*, S. Burn (Black East Indian); A. & J. Trickett; C. W. Brierley; S. & R. Ashton (Carolina).

PIGEONS.

CARRIERS.—Cup, W. Harvey. 2, F. Wiltshire, West Croydon. 3, J. C. Ord, Pimlico. *hc*, F. Cressley, Elland, Halifax; J. C. Ord. *c*, F. Crossley.

POUTERS.—1, F. Crossley. 2, W. Harvey. 3, H. Snowden, Great Horton, near Bradford. *hc*, W. Gamon; G. Sturgess, Leicester; H. Snowden; T. W. Kilburn, East Grimstead. *c*, E. Walker.

TUMBLERS (Almond).—1 and 3, F. Wiltshire. 2, F. Crossley. *hc*, F. Cressley; F. Wiltshire. *c*, W. Harvey; J. H. Ivimy.

TUMBLERS (Any other variety).—1 and 2, W. Harvey. 3, J. Fielding, jun., Rochdale. *hc* and *c*, F. Crossley (Agates and Kites).

BARBS.—1, W. Cannan. 2 and 3, F. Crossley. *hc*, F. Cressley; J. Firth, jun., Dewsbury. *c*, E Horner, Harewood, Leeds; J. Fielding, jun.

OWLS.—1, F. Crossley. 2, Miss F. Easton, Hull. 3, J. Fielding, jun. *c*, T. Eggleston, Halifax.

TURBITS.—1, J. T. Lishman, Bradford. 2, R. Bairstow, Bradford. 3, J. Hawley, Bingley. *hc*, E. Horner; F. Crossley. *c*, E. Horner; Miss F. Easton.

FANTAILS.—1, E. Horner. 2, H. Yardley, Birmingham. 3, J. C. Ord. *hc*, W. Harvey; W. R. Park; E. Horner; G. Sturgess. *c*, J. Lister, Keighley.

JACOBINS.—1, W. Cannan. 2 and 3, J. Thompson, Bingley. *hc*, E. Horner. *c*, E. Horner; J. C. Ord.

TRUMPETERS.—1, J. Hawley. 2, J. Firth, jun. 3, W. Harvey. *hc*, W. Harvey; E. Horner; W. Gamon; J. Thresh. *c*, E. Horner; S. A. Taylor, Coldfield, near Birmingham.

DRAGOONS.—1, W. Harvey. 2 and 3, W. Gamon. *vhc*, T. Smith. *hc*, E. Horner; H. Allsop; J. Thompson; J. Percivall; T. Lambert. *c*, W. Harvey; E. Horner; J. Thompson.

ANTWERPS.—1 and 3, J. Hawley. 2, J. Mills. *hc*, E. Horner; J. J. Bradley; H. Yardley. *c*, W. H. Mitchell, Keighley; J. Mills.

MAGPIES.—1, J. T. Lishman. 2 and 3, E. Horner. *hc*, J. Hawley; H. Draycott; J. T. Lishman.

ANY OTHER VARIETY.—1, J. T. Lishman. 2, E. Horner. 3, W. Harvey. *hc*, H. Draycott, Humberstone; H. Yardley; J. T. Lishman. *c*, T. Stretch (Nuns); G. Sturgess (Swifts).

SELLING CLASS.—1, E. Walker (Pouters). 2, J. Percival (Isabels). 3, J. Hawley. *hc*, Mrs. J. Cross (German Feather-footed Tumblers); J. Thompson; J. Lister. *c*, W. Harvey; F. Key, Beverley.

JUDGES.—*Poultry:* Mr. R. Teebay, Fulwood, Preston, and Mr. J. Hindson, Liverpool; *Pigeons:* Mr. W. Massey, Spalding, and Mr. E. Hutton, Pudsey.

ROYAL DUBLIN SOCIETY'S WINTER SHOW.

THIS Show was held in Dublin, December 7th, 8th, and 9th. The following is the prize list:—

DORKINGS (Silver-Grey).—1, W. Mulligan, Belfast. 2, G. Purdon, Killucan. 3 and *c*, Mrs. Warburton, Naas. *hc*, R. P. Williams, Clontarf. *Chickens.*—1, Miss Drevar, Blackrock. 2, *hc*, and *c*, Mrs. Warburton.

DORKINGS (Coloured).—1, Mrs. Hay, Cork. 2, Mrs. Warburton. 3, R. P. Williams. *hc*, Mrs. R. Clay. *Chickens.*—1, J. C. Cooper, Limerick. 2, W. Mulligan. *hc*, Mrs. Hay. *c*, Mrs. Warburton.

SPANISH.—1, Miss Drevar. 2, Hon. Miss D. Pennant, Bangor. *hc*, W. Mulligan; R. P. Williams. *c*, G. A. Stephens; R. P. Williams. *Chickens.*—1, Hon. Miss D. Pennant. 2, Miss Drevar. *hc*, W. Mulligan. *c*, Mrs. Melville.

BRAHMA POOTRA.—1, Hon. Miss D. Pennant. 2, Mrs. Warburton. Extra 2, Capt. Dowaman. *Chickens.*—1, G. A. Stephens, Dublin. 2, Capt Downman. *hc*, Hon. Miss D. Pennant. *c*, Mrs. Warburton.

COCHIN-CHINA.—1 and 2, F. W. Zurhorst, Dublin. *hc*, Hon. J. Massy; F. H. Green, Belfast. *Chickens.*—1, Mrs. Hay. 2, R. P. Williams.

GAME.—1, C. E. McClintock. 2, G. A. Perrin. *c*, Hon. J. Massy, Limerick. *Chickens.*—1 and *c*, G. A. Perrin. 2 and *c*, C. E. McClintock.

HAMBURGHS (Pencilled).—1, Hon. J. Masey. 2, C. E. McClintock. *c*, J. C. Cooper.

HAMBURGHS (Spangled).—1, Capt. Downman. 2, G. A. Stephens.

POLANDS (White-crested Black).—1 and 2, Miss Drevar.

LA FLÈCHE.—1 and 2, G. A. Stephens.

HOUDANS.—1, Mrs. Hay. *c*, G. A. Stephens.

CRÈVE-CŒUR.—1 and 2, F. W. Zurhorst.

ANY OTHER VARIETY.—1, J. C. Cooper (Saltans). 2, F. H. Green (Silver Polands). *hc*, Mrs. Green; F. W. Zurhorst (Silkies).

GAME BANTAMS.—1, F. W. Zurhorst. 2, W. G. Mulligan; *c*, G. F. D. Sutherland.

BANTAMS (Any other variety).—1, L. F. Perrin (Blacks). 2, J. K. Millner (Rumpless).

SINGLE COCKS.—*Dorking.*—1 and 2, R. Dove. *hc*, W. Magrath; G. A. Stephens. *c*, G. N. Furdon; S. Mowbray; J. Barlow; Mrs. Warburton. *Spanish.*—1, W. Mulligan. *c*, W. Mulligan; Miss Drevar. *Cochin.*—1, W. H. Perrin. 2, R. P. Williams. *c*, W. H. Perrin; J. C. Cooper. *Brahma.*—1, G. A. Stephens. 2, R. W. Boyle. *La Flèche.*—1 and 2, G. A. Stephens. *hc*, Capt. Downman. *Houdan.*—1, G. A. Stephens. 2, J. C. Cooper. *Crève-Cœur.*—1, P. J. Waldron. 2, J. C. Cooper. *Game.*—1 and *c*, G. A. Perrin. 2 and *hc*, C. E. McClintock.

TURKEYS.—1, J. C. Cooper. 2, Hon. J. Massy. 3, S. R. Magee. *hc*, E. A. Leale. *c*, J. Bourke. *Poults.*—1 and *hc*, Miss King. 2, J. C. Cooper. *c*, S. Mowbray. *Cocks.*—1, J. C. Cooper. 2, P. J. Waldron. *hc*, B. O'Connor.

GEESE.—1, 3, and *c*, Mrs. Warburton. 2, J. Bourke. *hc*, W. H. Perrin; Hon. J. Massy.

GEESE (Fat).—1, R. P. Williams. *hc*, Hon. J. Massy. *c*, Mrs. Warburton.

DUCKS (Rouen).—1, W. G. Mulligan. 2, R. P. Williams. *c*, J. C. Cooper.

DUCKS (Aylesbury).—1, R. P. Williams. 2, S. Mowbray. *hc*, G. A. Stephens; W. G. Mulligan. *c*, Miss Wallace.

PIGEONS.—*Carriers.*—1, C. F. Staunton, Cloudalkin. 2, J. McDonnel, Rathmines. *c*, Miss Caparn. *Cock.*—1, F. H. Green, Belfast. *hc*, A. Evans. *c*, E. M'Crae, Stdlorgan. *Hen.*—1, F. H. Green, Belfast. *hc*, C. F. Staunton. *Tumblers.*—1 and 2, R. Wallace, Donoybrook. *hc*, E. A. Leale; C. F. Staunton. *Fantails.*—1, E. M'Crea. 2, E. Leale; *hc*, E. Leale; Miss Caparn; A. Evans; C. F. Staunton. *Any other Variety.*—1, J. K. Milner (Barbs). 2, E. M'Crea (Ice). 3, C. F. Staunton (Turbits). *hc*, L. F. Perrin; C. F. Staunton. *c*, E. A. Leale; G. A. Stephens.

JUDGES.—Messrs. P. H. Jones, Fulham; J. Dombrain; and A. Comyns, Dublin.

TREDEGAR POULTRY SHOW.

THIS Show, which was held at Newport, Monmouthshire, on the 14th and 15th inst., was a success, marred only by the too late arrival of some of the best specimens of both poultry and Pigeons. So late, indeed, were some of these that the judging had been completed more than two hours, and what is more to be regretted, most of the late arrivals were birds which would have taken leading positions.

Some of the *Game* were very faulty as regards the feet, and soft in hand, but the winning pens were very fine, especially the first-prize Reds, and the pen of Duckwings that carried off the plate. Some of the *Spanish* were good, but roughness of face prevailed. The *Dorkings* were large-framed birds, and the dark *Brahmas* were also good. The cup for *Hamburghs* went to Golden-pencilled; this section was notably good. A cup was also awarded to *French* fowls; it brought an entry of capital birds, and the cup was borne off by one of the best pens of Crève-Cœurs we have seen of late. Game *Bantams* were good, but the Blacks were not so good as desirable, faulty combs being the order. White Bantams were much better than the Blacks, and Pekins and Sebrights won in the "variety" class. In the class for any other breed, Black Hamburghs were first, and Malays second. Aylesbury *Ducks* were a fair lot, but the Rouens were better, and the "variety class" was the most attractive of all, containing the most exquisite Mandarins, Carolinas, Shell, Musk, and Braziliams. *Geese* and *Turkeys* were much improved, as compared to those shown in previous years, both in respect to size and plumage. In the selling class there were forty-two entries, and many cheap lots were sold.

Of *Pigeons*, the Carriers and Ponters were very good in all particulars. Fantails formed a good class, both White, Blue, and Black being well represented. Of other varieties Nuns were first. Dutch Ponters second, and Red Swallows third.

GAME (Black or Brown-breasted Reds).—1, E. Aykroyd, Bradford. 2, Capt. Grove, Taynton. 3, W. C. Phillips, Worcester. *hc*, W. Bradley, Worcester.

GAME (Any other variety).—1 and Cup, H. C. & W. J. Mason, Drighlington. 2, W. C. Phillips. 3, E. Aykroyd. *hc*, W. Dunning, Newport, Salop; W. Nicholas, Caerphilly. *c*, G. Cole, Llanelly; E. Chilcott.

SPANISH.—1 and Cup, H. Beldon, Goitstock, Bingley. 2, J. R. Rodbard. 3, Tonkin & Tuckey, Bristol. *hc*, J. Stephens, Walsall; D. Lane, Gloucester.

DORKING (Any variety).—1, J. Martin, Claines, Worcester. 3, Miss A. B. Morgan, Dimlands, Cowbridge. *hc*, H. Pickles, jun., Earby, Skipton; L. Pattoo, Hillmore, Taunton; N. G. Russell, Kington. *c*, Lord Tredegar, Tredegar Park, Newport.

COCHIN-CHINA (Any variety).—1 and Cup, Miss J. Millward, Newton-St. Lee, Bristol. 2, Mrs. J. E. Brewer, Gorelands, Newport. 3, J. R. Rodbard, Wrington, Bristol. *hc*, Mrs. Allsopp, Worcester. *c*, J. Gwyone, Buckland; C. Taylor, Gloucester.

BRAHMA POOTRA (Light).—1, W. J. Cradock, Maindee, Newport. 2, J. Buckley, Llanelly. *hc*, T. A. Dean, Moreton-on-Lugg, Hereford. *c*, Mrs. Pearson, Cardiff; Lord Tredegar.

BRAHMA POOTRA (Dark).—1 and 2, Rev. J. Bowen, Talgarth. *vhc*, Mrs. Allsopp. *c*, C. Taylor, Gloucester; W. B. Etches, Whitchurch.

HAMBURGH (Gold-pencilled).—1 and Cup, J. Walker, Birstwith, Ripley. 2, H. Beldon. *hc*, W. Speakman, Nantwich. *c*, H. Pickles, jun.

HAMBURGHS (Silver-pencilled).—1, H. Beldon. 2, J. Walker. *hc*, J. Pearson, Bradford; Mrs. Allsopp. *c*, H. Pickles, jun.

HAMBURGHS (Gold-spangled).—1, S. & R. Ashton, Roe Cross, Mottram. 2, H. Pickles, jun. *hc*, H. Beldon; N. Marlor, Denton, Manchester.

HAMBURGHS Silver-spangled).—1, H. Beldon. 2, J. Walker. *vhc*, Mrs. Flynn, Hardingswood, Kidsgrove, Stoke-on-Trent. *hc*, J. Buckley. *c*, W. Bairstow.

POLANDS (Any variety).—1, H. Beldon. 2, J. Hinton, Warminster. 3, H. Laver, Colchester. *c*, J. Lankford, Brislington, Bristol.

HOUDANS.—1, C. Homfray, Newport. 2, J. G. Rose, Bath. *hc*, W. O. Quibell, Newark; Mrs. Llewellyn, Court Coleman, Bridgend.

ANY OTHER FRENCH VARIETY.—1 and Cup, C. Homfray (Crève-Cœur). 2, H. Wyndham, Wawne, Beverley (Crève-Cœur). 3, C. Taylor (Crève-Cœur). *c*, J. G. Ross (Crève-Cœur).

GAME BANTAMS.—1 and Cup, W. F. Entwisle, Westfield, Cleckheaton. 2, Mayo & Washbourne, Gloucester. *vhc*, E. Payne, Cardiff. *hc*, R. N. Barlow, Wrexham. *c*, W. Boutcher, Notting Hill, London; W. H. Tomlinson, Newark-on-Trent.

BANTAMS (Black, Clean-legged).—1, E. Cambridge, Bristol. 2, S. & R. Ashton. *vhc*, E. Cambridge. *hc*, H. Draycott. *c*, W. H. Tomlinson; H. Draycott.

BANTAMS (White, Clean-legged).—1, H. Draycott. 2, S. & R. Ashton. *hc*, Mayo & Washbourne. *c*, J. Walker.

BANTAMS (Any other variety).—1, H. Draycott. 2, Mayo & Washbourne.

ANY OTHER DISTINCT BREED.—1 and 4, Rev. W. Serjeantson (Black Hamburghs). 2, J. Hinton (Malays). 3, Mrs. Llewellyn (Sultans). 5, R. H. Nicholas (Black Hamburghs). *hc*, R. H. Nicholas (Black Hamburghs); N. Marlor (Black Hamburghs); S. Butterfield, Keighley (Black Hamburghs). *c*, J. M. Kilvert, Wakefield (Black Hamburghs).

GUINEA FOWLS.—1, Hon. F. C. Morgan, Newport.

DUCKS (Aylesbury).—1, Lord Tredegar. 2, C. Homfray. 3, E. C. Phillips, Brecon. *hc*, G. Thompson, Tregroes, Bridgend; Mrs. M. Jones, Newport.

DUCKS (Rouen).—1, Lord Tredegar. 2, H. J. Evans, Pwlloch, St. Mellons. 3, C. Homfray. *hc*, J. Cloud, Monmouth; H. Garsed, Park, Pentyrch; W. Cooper, Abergavenny. *c*, Rev. C. T. Salisbury, Newport.

DUCKS (Any other variety).—1 and 2, C. Homfray (Mandarins and Carolinas). *hc*, S. & R. Ashton Carolinas); C. Homfray (Brazilian); Lord Tredegar; Rev. W. Serjeantson. *c*, J. M. Kilvert, Ludlow.

GEESE.—1 and 2, R. Rees, Abergavenny. 3, D. Jenkins, Christchurch, Newport. *hc*, J. G. Holford, Buckland, Crickhowell; Hon. F. C. Morgan; Mrs. Matthews, Tredunnock, Llangibby.

TURKEYS.—1, Lord Tredegar. 2, Miss J. Milward. 3, Mrs. Allsopp. *hc*, Mrs. A. Stallard, Caerleon.

SELLING CLASS (Fowls).—1, W. J. Cradock, Maindee, Newport, Mon. (Brahmas). 2, R. H. Nicholas (Bantams). 3, C. Homfray, Newport (Houdans). 4, J. Skinner, Caerleon, Mon. (Dorkings). 5, S. Butterfield, Keighley (Black Hamburghs). *hc*, G. Thorne, Newport, Mon. (Andalusians); J. Skinner (Dorkings and Bantams); J. G. Holford, Buckland, Crickhowell, Brecon (Dorkings); Mrs. Llewellyn (Dorkings); R. H. Nicholas (Black Hamburghs and Silkies); J. Laybourne (Black Hamburghs); J. Percivall, Harborne, Birmingham (Polands). *c*, J. S. Phillips, Newport, Mon. (Black Red Game); E. Shaw, Plas Wilmot, Oswestry (Grey Dorkings); J. Buckley (Dorkings); D. W. J. Thomas, Brecon (Cochin-China); R. H. Nicholas (Game); H. H. Thompson, Hilmarton, Calne (Golden-pencilled Hamburghs); J. G. Holford.

SELLING CLASS (Ducks).—1, C. Homfray (Brazilian Ducks). 2, E. Shaw (Aylesbury Ducks). 3, J. E. Brewar, Gorelands, Newport (Aylesbury Ducks). *hc*, Mrs. Sketch, Lisswerry, Newport, Mon. (Barrow Ducks). *c*, Mrs. Llewellin (Brazilian Ducks); J. Skinner (Aylesbury Ducks).

SWEEPSTAKES FOR COCKS.—*Dorking.*—1, E. Shaw. *Game.*—1, F. Randell, Kidwelley, Carmarthen. 2, J. W. Jones, Newport. 3, Winwood and Hughes, Worcester. *Game Bantam.*—1, Mayo & Washbourne. 2, E. Payne. 3, E. C. Phillips. *Any other Variety.*—1, Wyndham & Ward, Salisbury (Crève-Cœur). 2, C. Homfray (Houdan).

PIGEONS.—*Carriers.*—1, J. C. Ord, Pimlico, London. 2 and *hc*, G. S. Hockey, Bristol. *c*, H. Yardley, Birmingham. *Pouters.*—1, H. Yardley. 2, Master C. W. S. Bulpin, Bridgwater. *hc*, H. Draycott. *Tumblers.*—1 and *hc*, Miss F. J. M. Bulpin. 2, H. Yardley. 3, J. Fielding, jun., Rochdale. *Fantails.*—1, W. H. Tomlinson, Newark-on-Trent. H. Draycott. *hc*, Miss F. J. M. Bulpin; J. E. Breward, Birmingham; W. H. Tomlinson. *c*, H. Yardley; Rev. W. S. Shaw, Bath. *Any other Variety.*—1, Master C. W. S. Bulpin. 2, H. Yardley. 3, H. Draycott. *hc*, T. A. Dean, Moreton-on-Lugg, Hereford (Nuns).

The Judge was Mr. E. Hutton, Pudsey, Leeds.

ASHFORD POULTRY SHOW.

THIS was held on the 13th and 14th inst. The following is the prize list:—

Parlett, Great Baddow. *hc*, R. Cheesman, jun., Westwell, Ashford. *c*, G. W. Greenhill; T. Perkins; R. Cheesman, jun.

DORKINGS (Silver-Grey).—1, Miss Hales. 2, J. B. Plumptre, Goodnestone. *Chickens.*—1 and 2, J. B. Plumptre. *hc*, F. Cheesman, Ashford. *c*, F. Cheesman; Miss M. Plumptre, Canterbury; Rev. T. E. Cato, Wye.

DORKINGS (White).—1, A. Cobb, Faversham.

DORKINGS (Any variety).—*Hens.*—1, Rev. T. E. Cato. *hc*, G. W. Greenhill. *c*, J. B. Plumptre. Extra, F. Parlett. *Cock.*—1, Miss Pittock. 2, F. Parlett. *hc*, F. Cheesman; G. W. Greenhill. *c*, J. B. Plumptre.

SPANISH.—1, Nichols & Howard, Camberwell. 2, W. Rossell, Ashford. *Chickens.*—1, Nichols & Howard. 2, F. James, Peckham. *hc*, R. West, Maidstone. *c*, J. B. Plumptre; W. J. Hammond, Ashford; C. F. Hore, Tunbridge. *Cock.*—1, R. West. *hc*, F. James. *c*, C. W. Hammond.

COCHIN-CHINA (Cinnamon or Buff).—1, Miss Hales, Canterbury. 2 and *c*, W. F. Harvey, Thruxted.

COCHIN-CHINA (Any other variety).—1, T. G. Ledger, Folkestone. 2, Miss Hales. *c*, J. H. Dawes, Moseley Hall, Birmingham.

BRAHMA POOTRA.—Cup and 1, — Herbert. 2 and 3, Miss Hales. *c*, W. F. Brook, Wye; E. C. Dering, Surrenden Deering; — Herbert; J. H. Cuff, London.

GAME (Black and Brown Red).—1, S. Matthew, Stowmarket. 2 and *c*, J. Jeken, Eltham. 3, W. F. Harvey. *hc*, R. Hall, Cambridge. *Chickens.*—1 and Cup, W. Adams, Ipswich. 2, S. Matthew. 3, R. Hall. *hc*, W. F. Harvey.

GAME (Any other variety).—1, S. Matthew (Duckwing). 2, F. Kipping (Duckwing). *Chickens.*—1, S. Matthew (Duckwing). 2, J. H. Dawes (Black). *hc*, E. Rice (Duckwing). *c*, J. Jeken. *Cock.*—1, J. Jeken. 2, J. H. Bayley, Ashford (Black Reds). *hc*, R. Hall; E. Rice (Black-breasted Red). *c*, T. G. Ledger.

HAMBURGH (Golden-spangled).—1, T. Penfold, Newhaven. 2, R. West.

HAMBURGH (Silver-spangled).—1, T. Penfold. 2, F. Elliott. *hc*, R. West. *c*, M. Dorman, Ashford.

HAMBURGH (Gold-pencilled).—1, C. Havers, Ingatestone. 2, R. West. *hc*, Usborne & Worger, Ashford. *c*, Miss Hales.

HAMBURGH (Silver-pencilled).—1, withheld. 2, R. Fowle, Wingham.

POLISH.—1, D. Mutton, Brighton (Black with white crest). 2, E. J.

Reeves (Gold). *hc*, G. W. Boothby, Louth. *c*, Miss Hales (Golden-spangled); G. W. Boothby; D. Mutton (Black with white crest).

Crève-Cœur.—1, Rev. H. H. Dombrain, Westwell Vicarage, Ashford. 2, T. G. Ledger. *hc*, W. Dring.

Houdan.—1, W. O. Quibell, Newark. 2 and 3, Hill & Co., Brighton. *hc*, G. Mills; W. O. Quibell, Newark; W. Dring; J. Norwood, Mersham. *c*, G. Mills; F. Elliott.

Bantams (Gold and Silver-laced).—1, Miss A. Hodson, North Petherton.

Bantams (Black, White, or any variety).—1, Miss E. J. N. Hawker, Tunbridge Wells. 2, D. Mutton. *hc*, J. Barnard, Staplehurst; J. H. Bayley. *c*, R. Fowler.

Game Bantams.—1, F. James. 2, J. B. Plumptre. 3, H. Dowsett. Pleshey.

Ducks (Aylesbury).—1 and *hc*, C. Havers. 2, W. Jacob, Shepherdswell. *c*, G. W. Greenhill; Miss Hales.

Ducks (Rouen).—1, C. S. Hardy, Canterbury. 2, W. Jacob. *hc*, W. F. Harvey; Lady F. Bushby, Kingston Hill; F. Parlett.

Geese.—2, Miss Hales. *hc*, D. Swaffer, Kingsnorth; Mrs. Powell. *Goslings*.—1, Miss Hales. 2, Mrs. Powell. *hc*, D. Swaffer; Miss Hales.

Turkeys.—1, Miss Hales. 2, J. Foord. *hc*, W. H. Mold, Bethersden. *Poults*.—1, T. Harvey. 2, W. B. Sharpe, Cranbrook. *hc*, T. Harvey; W. H. Mould; J. Foord, Ashford.

Any other Variety.—1, C. Ayers, Canterbury (Gnelder or Breda). 2, Hills & Co. (Gangesian). *hc*, Miss Hales (Silkies). *c*, G. Mills (La Fleche); F. Elliott, Dymchurch (Black Hamburgh).

Selling Class.—1, G. Mills, Woodville, Dover (La Flèche). 2, C. F. Hore (Brown Red Game). 3, R. Cheesman (Dorking). *hc*, J. B. Plumptre (Dorking); G. W. Greenhill (Dorking). *c*, Dr. Beet, Ashford (Houdans); J. B. Plumptre (Silver-Grey Dorkings); T. Perkins (Spanish and Houdans); W. P. Forth, Ashford (White Bantams); J. Rogers, Hastings (White and Black Cochins); Col. Deedes, Hythe (Grey Dorking).

Extra Local Prize (Houdan).—*Chicken*.—1, G. Mills.

Pigeons.—*Carriers* (Any colour).—1, W. Foster, Ripple House, Deal. 2, J. F. Jenks, Canterbury. *Tumblers*.—1, W. Igglesden. 2, F. Elgar, Sandwich. *Fantails*.—1, G. W. Greenhill. 2, F. Elgar. *hc*, A. A. Vander Meersch, Forest Hill; G. W. Greenhill. *Any other Variety*.—1, Lady F. Bushby (Blue Runts). 2, J. Bowes (Owls). 3, E. C. Dering (German Helmet). *hc*, W. Igglesden, Ashford (White Trumpeters).

KILMARNOCK POULTRY, PIGEON, AND CANARY SHOW.

Our friends in the north are certainly progressing. The fanciers are waking-up again with renewed and increased spirit, and as our exhibitions come round those who have been so long in retirement appear with the produce of their summer's labours, setting them on the tables of our shows to the surprise of their brethren, and the admiration of visitors.

Kilmarnock has taken a decided step in advance this year, and if ever a Committee had reason to be gratified by the successful termination of their work, it is that of the quiet and industrious manufacturing town of carpets and blue bonnets. Last year the Show was held in the Market Hall, behind the Corn Exchange, a very large square building, roofed with glass, and the Exhibition comprised 182 pens of poultry, 158 pens of Pigeons, and 127 cages of Canary birds. This year the Show was held on the 27th ult., and the entries increased to such an extent that the Committee had to engage not only the Hall, but the Corn Exchange as well, a large and elegant building communicating with the Hall by an easy flight of steps. The Market Hall was devoted to the poultry, of which 259 pens were exhibited; and the Exchange which was neatly arranged after the manner of the Glasgow Show, having pens of the same size and shape, contained 241 pens of Pigeons, with shelves against one wall on which were placed 202 cages of Canary birds. One healthy sign of this Show at once caught the eye—so far as we could observe there were only three empty pens in the whole Exhibition, and we could not but admire the conscientious care bestowed on the specimens sent for exhibition. They were not only accommodated with large and roomy pens, but systematically fed and watered, and a sufficient staff of police, besides the members of the Committee, kept a watch over the whole.

The extra prizes awarded at this Show, like those at the Johnstone Show, were something new—viz., timepieces, some in marble, others in gilt stands—next to money certainly one of the most useful as well as ornamental articles that could be given. The appreciation of these prizes was at once seen by the numerous entries for them.

Poultry.—*Spanish* was a very excellent class, the prize birds being remarkable for their combs and purity of face. Many elegant and promising birds stood in this class; the special prize being for the best cock or cockerel, was awarded to the second-prize pen, the cockerel contained therein being the best.

Dorkings.—The first-prize hen was the best bird in the class, and though the entries were not numerous, the birds as a whole were good. The third-prize pen contained birds of great promise, and they will, no doubt, take a higher place at another time. Of *Brahmas* or *Cochin-Chinas* there were some fair birds. The cock which gained the first prize and also the timepiece for the best cock in Classes 2, 3, and 4, seemed to us to be rather long in the limb. *Scotch Greys* were a very good class, but breeders should endeavour to produce birds with a deeper black and purer white than those which are now generally exhibited. Golden-spangled *Hamburghs* were remarkably good, and must have given the Judges considerable trouble. Pen 85, commended (W. A. Hyde), was very much admired, and had it not been for the faulty ear of the hen might have had a more honourable place. Golden-pencilled Hamburghs were also very good; the prize birds bid fair to hold their place at any show. Among Silver-spangled Hamburghs were some excellent birds. The first-prize cock, which gained also the timepiece for the best cock in Classes 7 and 8, was faultless, with the exception of having a rather heavy comb. The hen he was matched with we considered a little too dark. The third-prize hen was in marking almost perfect, and many other birds, had they been well matched, would have caused the Judges no little trouble. Silver-pencilled Hamburghs were also very good, the hens in some cases being of great merit. As a whole they were much admired by visitors. *Polands* constituted but a weak class; the first and second-prize pens were, however, very good. Polands being so constantly hoodwinked, and, therefore, so unable to take care of themselves, do not seem to be kept in any great numbers at the present day.

Of *Game* there was a fair class containing some fine birds but badly matched, a great drawback to exhibitors. The first-prize cock was a good and powerful bird, but hardly fine enough in the head. Many of the smaller birds were very elegant in form. *Game Bantams* were as usual the largest and best class in the Show, and the Judges had great difficulty in making their awards. The elegance of shape and grace of motion seemed to attract the lady visitors to this pretty class. Black Bantams with the exception of the prize birds were not quite so good as we have seen. Of Bantams, "Any other variety," there was a very pretty class; the variety of feather and shape afforded a complete contrast to all the other classes, and from the elevated and isolated position of the pens the class formed a pretty little show of itself.

Of Aylesbury *Ducks* indifferent birds were shown; a cross would be of great advantage to the exhibitors. Among Rouen Ducks the prize birds were as fine as we have seen at any show in the kingdom.

Pigeons.—We were not prepared for the sight presented to us by the extent of this department; both in numbers and quality it would have done credit to a city show. The Ponter pens were arranged opposite the entrance, and presented a most imposing line. Both in the old and young classes of Ponters there were birds of the most perfect form. In many cases the markings were almost perfect; as a rule the colours were good, Reds being the worst. The most fastidious fancier of Ponters might have stocked his loft with birds from this Show. An unusual appearance attracted us to a pen in the old class (Ponters any colour), containing a pair of splendid birds in high training. They were valued in the catalogue at £50. Worth the money? Well, but they were artificially coloured to the very eyes, and after all they would have held their position had the colour and "finish" been left with the vendors. This was not the only pen tampered with in this class; but for the present we abstain from publishing names, in the hope that some step will be taken on an early day which will put an end to this dishonest practice. We are sorry to say that in the second class, "Ponters bred 1869," several birds had also been tampered with, and some of the pens contained old birds. A placard was posted in the Hall, which read as follows: "Young Ponters. Many birds in this class disqualified as old, also for being tampered with." Space does not allow us to describe as we could desire the numerous specimens of merit exhibited. The fanciers in the west of Scotland are advancing in Carriers; the class for these was not inferior to that for the Ponters, and the principal part were entered by Kilmarnock fanciers. The Blacks were certainly the best; some single birds in Duns very fine, but, unfortunately, several pairs were ill-matched. The young class was the best we have ever seen at any local Scotch show. We were rather doubtful that the cock in the first-prize pen (Dun) was a last year's bird. The second and third-prize pens, shown by Mr. White, Paisley, were beautiful; both black heads and necks of exquisite form, and the fine, bold, arrow-shaped bills are sure to become the perfect "box" as they become older. There was a good class of Short-faced Tumblers, Mr. Fielding carrying off the first prize, and Mr. Mair, Kilmarnock, the second; but some of the pairs were not in very good order. Common Tumblers were an excellent class. We were glad to see the prize money for this class the same as for the others, as it encourages young fanciers to prosecute this pleasant and instructive pastime. Almost every variety in colour and marking was here exhibited. Among the Fantails stood some rare specimens. The first-prize birds had saddled tails, and were large, and their motion perfect. One bird, shown by Mr. Kerr, Kilmarnock, was a gem—pure white—but it had a miserable mate. Jacobins were a poor class. We are rather fastidious as to this bird, and seldom see the elegant Swallow-shaped bird of olden times. Barbs were a very good class; the Blacks by far the best. Of Trumpeters several superior pairs were shown; all were perfect in the feet, some wanting in rose and crest. This class of birds is decidedly improving. There was a good deal of dressing among the Nuns, and several birds were disqualified. The "Any other variety" class contained a diversity of beautiful Pigeons, all in fine order. Without doubt, the most interesting were the little white foreign Owls, shown by Mr. Fielding, with their sweet little chubby faces. The same birds appeared formerly at another show, and an old and ardent fancier, on looking at them then, said "They are just like things made for kissing." By-the-by, he was, is, and is likely to remain, a bachelor.

The Canary department was a most interesting one; the birds all so tame, clean, and in perfect feather. We think it a pity that the Glasgow fancy Canary is not better known in the south; the small bills and beautifully rounded heads, narrow shoulders, and long tapering tails, all forming one perfect curve—moving on long, neatly-set limbs, and displaying a grace of form and motion which could not

have been attained but by dint of long and careful breeding. The Mules bred from this breed of Canaries were also very handsome in shape. There were, however, two classes of Canaries which we missed, and if they were introduced into our northern shows would give, we feel sure, additional interest both to fanciers and visitors; we refer to the Belgians and Lizards. The former have been much used for the improving of other breeds, and are, we think, well worthy of cultivation; the latter, so beautiful in colours and markings, so hardy and easily managed, and forming such a contrast to other breeds, would come in as a further attraction. We wish our Kilmarnock friends all success in time coming, and would recommend them, if possible, to allow the Judges a full day for their work, and the public the day following to enjoy the exhibition.

☞ We published a list of the awards last week.

RABBITS AND THEIR VARIETIES.

We have heard much respecting exhibited Rabbits of late, and many things have been said about judges, committees, and the officers in connection with exhibitions generally. All this will tend to a satisfactory result, I have no doubt, and so all will be pleased. I have often thought of a method of judging Rabbits that might be more in accordance with a correct conclusion as to their merits, regardless of any reference to the catalogue. All the judge requires, in my opinion, is the schedule of prizes, and for what they are offered—length of ear, heaviest weight, &c.; and with that knowledge only he may commence his duties, and in total ignorance of the owners' names. There could then be no remark that the judge had given the prize to the owner instead of the Rabbit, as is too often heard, especially when the judge goes the round of the pens with catalogue in hand, for in it there is no information that he requires. The specimens are there, and the only question with him is which is the best in its class.

The Himalayan, or, as the word implies, a "palace of snow"—this "furry friend," as some enthusiastic admirer of the Rabbit family is pleased to designate his pet, is found in great numbers on the chain of mountains which extend 1800 miles from the Burrampooter, in Assam, to the western extremity of the Hindoo-Koosh, in Cabul, and it is asserted that this is a sacrificial animal with the Chinese, who annually sacrifice thirty thousands of them, with prayers that their crops may be as prolific as Rabbits. Hence we at times find them spoken of as the Chinese Rabbit, also as the Black-nosed Rabbit. They are found and reared on the Continent; and I have seen them labelled at exhibitions as Antwerp Rabbits, and many are imported into this country from that city. Egyptian Smut is a name also applied to this neat specimen, and if variety of names adds to the intrinsic value or interest of this little animal, the Himalayan is highly favoured. Perhaps no specimen presents a more decided appearance than it does, or has the points of excellence more evident to a judge. The darker the extremities are the more valuable, and a greater certainty of a prize irrespective of the size; yet I have seen very imperfectly marked specimens at shows carry off prizes because of their corporeal magnitude, yet with very grey extremities.

I may here remark what all keen observers of this variety may also have noticed: that at times the extremities, especially the feet, undergo a great change, and for three months at a time present anything but the deep dark shade so desirable. This change occurs when the moult is in progress, and many an anxious exhibitor has been disappointed at finding his probable prize-winner looking anything but black enough in the face to come off with honours.

I would caution all owners of this variety to avoid chloride of lime as a disinfectant in the hutch, it being too strong, and producing a slight change in the shade of the feet. I have tried many experiments in this particular. This variety is by no means large—say 6 or 7 lbs., if of the pure kind. I have obtained very large specimens up to 9 lbs. by crossing with a large Polish Rabbit, but some five or six generations must elapse before the true dark and glossy nose and other extremities are fully presented. I would advise all rearers of this variety to keep to the pure specimen as the most certain to afford satisfactory results.

In the marking no white foot should be seen; yet it so happens that half the foot, or at times the entire foot, is almost white, which is a decided objection, and must always exclude the animal from any show, although in other respects a fine specimen.

The Himalayan is in my opinion one of the most decided varieties we have, if not the most so, as no deviation from the dark shade of the extremities can be allowed, and the judge makes this dark shade the real "point" of merit; and no Rabbit less than six months old ought to be exhibited, as its true marking is not perfect earlier, or so seen in many instances. This is not a variety to experiment with to any advantage, and when the extremities are grey, especially the ears and nose, be assured that some ancestor not many generations back was pure white, or nearly so.

The Himalayan is of a kind yet spirited disposition, not, perhaps quite so tame with the same amount of petting as the Dutch or Angora, yet a very interesting variety. I have no doubt but many of my Rabbit-loving readers may have noticed with what attention one of this variety, especially a doe, will look at one and move its head about as it does, and one is much interested by the appearance of its fully opened and beautiful pink eye, which seems to watch every motion. The doe is an excellent mother, and manifests great care for her young, generally from six to ten at a litter. The fur is valuable, and at times designated mock ermine; it is finer and more lustrous than that of the common white Rabbit, and on the Continent, more particularly, it is valued by the furriers. This specimen and the Silver-Grey undergo, perhaps, the greatest change from birth to maturity of any variety, the Himalayan when leaving the nest being quite white to all appearance, except the extremities, which only an accustomed observer could detect as of a slightly darker shade when a month old, and the Silver-Grey quite black when of the same age.

The Himalayan is at times, like other varieties from warmer climates than our own, liable to a gathering of scurf in the ear, or "ear gum," which at times, if not attended to, proves fatal. I well remember losing one of my first specimens, which was brought by a friend from Canton, from this cause. The most effectual remedy is to sprinkle in the ear a little flowers of sulphur, after first loosening the scurf with, say, a feather, avoiding pain as much as possible, as the ear is very sore at times; a cure will be effected in a week. I hope ere long to say a few words about the Silver-Grey.—Charles Rayson, *York Mount, Prestwich.*

DR. PREUSS ON FOUL BROOD AND INFECTION.

In compliance with the request of the Baroness von Berlepsch, I have now the pleasure of redeeming the promise which I made in "our Journal" of the 12th August, by presenting to its readers in an English dress a full elucidation of the views entertained by Dr. Preuse, of Dirschau. The Baroness in writing to me characterised it as an "important article," and in this opinion I fully concur. It is, indeed, a most important paper, interesting and suggestive to the last degree, and especially to the medical profession, since it briefly but clearly describes much of what has been effected by the profound thinkers and untiring investigators of Germany towards solving one of the most momentous, and hitherto one of the most inscrutable problems to which the human mind could apply itself.—A Devonshire Bee-keeper.

ON THE SMALLEST MICROSCOPICAL FUNGI, ESPECIALLY THE FOUL-BROOD FUNGUS.

(*A Contribution to the Theory of Foul Brood, its Nature, Cause, Prevention, and Cure.*)

In the German Bee Journal of the 1st October, 1868*, I communicated the results of the microscopical examination of foul brood, and declared that a fungus belonging to the species Cryptococcus was present therein. I also stated, and laid great stress upon, the exactness with which such investigations should be made; described how we placed only a particle of foul brood no larger than a grain of sand on a glass slide, diluted this with a minute drop of freshly-distilled water the size of a millet seed, and covered the whole with a thin glass about the substance of a poppy leaf, so as to bring it under the microscope, which latter it was absolutely necessary should be of a very superior character.

Should any of your correspondents state that they have looked for the foul-brood fungus with a good magnifier, and have not found it, the result may readily be explained by the fact that small microscopes, which are sufficient for the investigation of Trichinæ, are perfectly useless for the discovery of Cryptococci. The size of Trichinæ, as compared with the foul-brood fungus, bears the same proportion as that of a large eel to a millet seed, and every expert can detect the former with the

* *Vide* Journal of Horticulture of 22nd October, 1868.

naked eye as soon as it is dissected out and placed on a glass slide. The smallest instrument which is serviceable for the observation of foul-brood fungus is the medium-sized microscope, manufactured by Schieck, which has a magnifying power of 150 diameters*. Excellent instruments are also supplied by Merz, Zeis, Hartnach, and others, in Munich.

It has already been stated that the Cryptococcus is round, and that it has a diameter of 0·002 millimètre (1-1095th of a line). After these observations had been published, I found during the autumn of last year that many foul-broody cells contained also numerous much more minute bodies, which, under the many-thousandfold magnifying power at which Cryptococcus appears of a globular form, assumed the same shape, and were identical in character.† Their diameter may be stated at 0·004 millimètre (1-5500 of a line). It is this form that Hallier has denominated the Micrococcus, seed-cell, or seed-leaven. I have sent pieces of foul-broody comb to Dr. Bail, Director of the Dantzic Naturalist's Society, so celebrated as a microscopist, and especially for his scientific works on mycology, and he has satisfied himself of the existence therein of numberless specimens of Micrococcus. These fungoid forms have also been shown by me to the most distinguished bee-keepers in this district—Wannow, of Gütland; Lohse, of Stüblau, and others. In the annexed engraving the small bodies *a* represent Micrococcus, and *b* the Cryptococcus of foul brood.

Fig. 1.

The science of mycology has been brought to great perfection by the careful investigations of Pasteur, Kloh, Bail, Hoffman, and others, and especially by the works of Professor Hallier, of Jena. Hallier's "Phenomena of Fermentation; an Investigation into Fermentation, Putrefaction, and Decay," Leipzig, 1867: his "Vegetable Parasites of the Human Body," Leipzig, 1866: "The Cholera Contagion: Mycological Investigations, addressed to Physicians and Naturalists," Leipzig, 1867: and finally, "Parasitological Researches; referring Measles, Famine-fever, Typhus, Small-pox, Cow-pox, Variola in Sheep, &c., to Vegetable Organisms," Leipzig, 1868—are especially recommended to those who wish to make themselves masters of the subject.

We sometimes find this formerly unnoticed organism play a friendly and beneficent part in nature, as, for example, when it becomes the medium of fermentation; but far more often does the minutest form of Micrococcus spread devastation and death among plants, animals, and men. Who, before the invention of the microscope, could have believed that the actual growth of mildew—the lowest form of vegetation—could be made visible to him! The microscope has shown, moreover, that this is the highest degree of development of still lower forms; that besides the stalks there are spores, which are small bulbs scarcely visible to the naked eye; and that each spore when greatly magnified presents itself as a capsule, which when it bursts throws off thousands of sporules, which are capable of motion if brought into contact with fluids. These sporules are the Micrococcus, which, therefore, correspond to the seeds of higher organisms. As there are many kinds of mildew and fungus, so also the number of varieties of Micrococcus is just as great. These are, however, so excessively minute that the eye fails to distinguish one from another, even when assisted by the most powerful microscope; only by what proceeds from them, and which at last assimilates itself to the parent stock, can the difference be detected.

The Micrococcus belongs to the uni-cells. With these is reached the boundary line of creation, within which lies the whole secret of what we call vegetable life. We need only recite one great fact, which forms an immeasurable gulf between this type and the inorganic: *It is capable of multiplying itself.* A cell consists of a cortex and a kernel, which in the Micrococcus are in close contact with each other. By means of its peculiar power, which we call vital force, it exercises an attraction upon the surrounding substance, which serves it as food. *Cortex and kernel enlarge, both divide, and thus one cell becomes two, by each of which the same process is repeated. The Micrococcus can now either increase ad infinitum by dividing itself in two in this manner without assuming a higher type, and remaining unchanged for years may spread itself over vast tracts of country* (upon which subject we shall have more to say farther on), *or it may develope into higher forms.*

The next higher form of development is this: That the Micrococcus forms a hollow space (vacuole) between the kernel and cortex, and that the minute dot-like body changes into a little bulb, in which we can perceive a kernel. This form represents Cryptococcus (*fig.* 1, *b*). It multiplies itself, precisely like the Micrococcus, by division. It forms on one part of the cell a bud-like elevation, which rapidly increases, and ultimately separates itself and forms a new cell (*fig.* 1, *c*), after which the same process is continued.

Both Micrococcus and Cryptococcus are comprehended under the name of fermentive fungus.

The two kinds of increase which have been mentioned take place without the admission of air. Their essential requisites are a temperature between the boiling and the freezing points, moisture, and nitrogen. The development of Cryptococcus flourishes under fewer conditions than that of Micrococcus, if only it be surrounded by strong nitrogenous elements.

We now come to a still farther development of the lower fungoid forms.

In Micrococcus and Cryptococcus the cells multiply with extreme rapidity. Under certain conditions, especially with but slight access of air, such as occurs under the bark of trees and beneath the scarf-skin of animals, the cells remain hanging together, and we obtain the form which we call Oïdium, and which we see beginning to show itself at *c*, *fig.* 2, and completely formed in *fig.* 3.

Fig. 2.

Fig. 3.

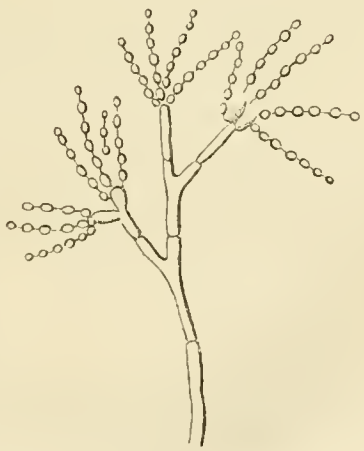

Fig. 4.

Fig. 5.

With free access of air we at last witness the formation of the perfect mildew (*fig.* 4); rapid development is already going on at the ends of the cells, where little spores, shells whose contents are innumerable granules of Micrococcus, form themselves (*fig.* 5). Thus each fungus runs through four principal stages—Micrococcus, Cryptococcus, Oïdium, and Mildew.*

*F. W. Schieck & Son, 14, Hallische Street, Berlin, supply this microscope for 100 thalers (about £15). The largest manufactured, with a magnifying power of 2500 diameters, costs 200 thalers. The smallest pocket microscope, magnifying 200 times, and sufficient for observing Trichinæ, 10 thalers.

† We often find similar but larger ellipsoidal corpuscles with the Cryptococcus. These are the organic cells of the larva, which may be seen by the thousand if we crush the egg of the bee and place it under the microscope.

* I purposely omit the intermediate stages, such as Arthrococcus, Torula Hormiscium, Leptotrix, &c., which occur during acetous fermentation.

The foregoing figures 2, 3, 4, and 5, show the development of the common brush-mildew, Penicillium crustaceum; and we shall again return to the distinctive character and appearance of the simpler forms of this mildew.—Dr. Preuss, *Sanitätsrath.*

(To be continued.)

BEE-HUNTING.

The custom of bee-hunting used to be, and is yet to some extent, a favourite pastime among the inhabitants of the Green Mountains. To hunt successfully requires a thorough knowledge of the bee and all its habits; and, therefore, like any other game, those who love the sport pride themselves upon their proficiency. The hunter starts out armed with a small box with a sliding cover, a card of honeycomb, and a small bottle of honey, molasses, or something suited to the taste of the bee. When near the locality of wild bees, he fills the comb with the honey from the bottle, places it in the bottom of the box, and hunts for a bee upon a flower, which, when found, he brushes into the box, at the same time closing the lid. The prisoner will buzz for a while, and then goes to filling his sack from the honey in the bottom of the box. The hunter then places the box in a favourable position for seeing it, and slides back the cover. Having "filled," as the hunter says, the bee flies straight to his tree, and returns to fill again, bringing others with him. Oftentimes these workers increase so rapidly that a steady stream will be seen going to and from the box, which can easily be followed to the tree at once. Frequently large deposits of honey are found in this way, which the little workers show as much bravery in defending as industry in gathering.

There lived in the town of R—— an eccentric character, "Uncle Joe," whose particular pride was in being thought a master of this sport. Once, on the approach of the hunting season, he went out, as usual, armed with bee-box and honey-bottle, and soon had a worker caught, but somehow he showed an utter indifference to Joe's honey. He let him go and caught another, who behaved in like manner; and so he spent the day, every bee refusing his free lunch, until Joe really thought the bees all crazy or himself dreaming, for surely he never knew the like before. In utter amazement he gave up the job, and went home. Meeting his "better half" at the door he gave her his traps to put away, told her his luck, which he was disposed to consider an ill omen, and waited for her to speak, which she soon did. Holding the bottle up before her, she exclaimed, with a twinkle in both eyes, "Well, well, Joe, if you havn't gone and taken my castor-oil to line bees with!" Joe looked, and seeing his honey-bottle untouched, saw the joke and wilted, for he knew that he would never hear the last of it, as one of his neighbours' boys happened to be present.

That evening as Joe, rather happy from the effects of something taken to relieve his chagrin, strolled into the village hotel, where a few of his neighbours were congregated, one who never let a chance slip to give Joe a hit, and who rarely got the better of him, related Joe's experiment, and turning to him with an air of having at last got his enemy in a tight place, asked Joe if he hadn't better treat on that? Joe steadied himself by a chair, and when the laugh had subsided so as to be heard, said with a very knowing look, "Gentlemen, there is no mistake about that. I wasn't trying to hunt those bees; I was only doctoring them. Bees always have to be physicked before they will work well!" This brought the house down, and although Joe did not stand the treat, some one did, and he had to be helped home.—(*Harper's (American) Magazine.*)

OUR LETTER BOX.

Hamburgh Fowls, Comparative Hardiness of (*J.*).—Most people consider there is no difference but colour between the Golden and Silver-pencilled. We, however, always fancy the former are the stronger. We are sure they do better with us. We consider Partridge Cochins much more fitted for confinement than either of them. Barley meal or ground oats make an excellent change with barley, and it may be profitably varied by substituting two or three times per week a meal of Indian corn.

Black-legged Bantam (*Poplar*).—Your description of the Bantam hen is not that of a Brown Red Game. Her black plumage should be striped with yellow on the hackle. You must put her to a Brown Red cock, and though she lacks part of the plumage, she will throw some good chickens. Breeding from a Black hen, you should choose a cock with plenty of colour.

Lice on a Duck's Head (*Inquirer*).—We do not know the properties of Keating's insect-destroying powder. We know that flowers of sulphur will kill lice. Still more efficient is camphor. We cannot say whether the coloured application will stain the feathers. If you are sure the parasites are confined to the Duck's head, they can be easily destroyed. Having ascertained their locality exactly, form a ring just below it with oil, laid on thickly down to the skin, and then powder the head with powdered camphor.

Comb of Spanish Cockerel Lopping (*J. T. T. and T. Sims*).—Spanish cocks' combs lop over from two causes; one, over-feeding on stimulating food, the other from lack of condition. It is a rare occurrence for a comb that has once fallen over to regain its original position. Good barley is good food; Indian corn is good for a change; we are not friendly to potatoes, and when we have seen them mixed with meal, the meal was almost imperceptible. A few peas do good to Spanish at times. No grass will grow well in a yard where the sun never penetrates, but the sweet-scented vernal grass, Anthoxanthum odoratum might. We have tried to grow grass in London, but it always degenerated into moss and spongy fungus, that seemed to have no property but that of holding water. Your best plan would be to cover your yard with road grit or other loose, dry stuff, and then to contract with some man in the country to bring you good quantities of growing grass, dug up with plenty of soil.

Points of Dark Brahmas (*Idem*).—It is not so much the heavy weight as the bright condition of the birds, that is necessary for success at a show. Although scales are sometimes used, yet, as a rule, competent judges eschew them. Feed on ground oats, good barley, and barley meal, and in very wet cold weather give them some bread and ale.

Fowls for Egg-producing (*Two-year-old Subscriber*).—We have always considered the Spangled stronger birds than the Pencilled. There is no difference but colour between Golden and Silver.

Age of Birds at the Birmingham Show (*Scrutator*).—You are in error; the birds were aged, as printed at the time of entry some months since. If you had ever acted as judge at a large show, you would know too much on the subject to allow you to think as you do. So far from overlooking defects, the judges are too happy to discover them to enable them to lessen the number of the competitors. The awards are given in by one judge, who is checked by the other two. They are copied into properly-ruled books by four secretaries. If any mistake occur, it is in spite of seven persons whose interest it is to prevent it.

Incubator (*A Reader of the P. C.*).—Do not employ it. Keep a few Cochin-China hens. They are often broody, and are good mothers. They may be with your Crève-Cœurs.

Houdan Cock at Birmingham.—The third-prize Houdan cock was priced in the catalogue £2 10*s.*, consequently could not have been sold for a less sum at auction, and we are informed that the actual price he was sold at was £4 10*s.*, being £2 more than the price put upon him.

Will Lettuces Kill Pigeons? (*A Reader of the Journal*).—Lettuces are slightly narcotic, but we should not think that any Pigeon would eat a sufficient quantity of them to cause death. If Pigeons were absolutely kept from all other food such a result might possibly happen, but as they are by nature granivorous birds, they would only take a little lettuce, and turn again to the seed-hopper.

Address.—"*C. R.*" would be obliged by the address of Mr. F. Schröder, formerly of Rickmansworth.

Tortoise in Winter (*L. B.*).—It hybernates—that is, remains torpid during the winter, and requires no feeding.

Associating Hens of Different Varieties (*H. N. A.*).—We have no further information than that contained in the communications we have published. Whether such association causes a hen of one variety to produce chickens partaking of the characteristics of other hens associated, must be determined by more facts and more certain experiments than are yet recorded. You ask our opinion, and our opinion is that such association has no influence over the form or plumage of the chickens. You will much oblige us by informing us if the chickens hereafter produced from your Cochin-China hens at all partake, or do not partake, of the plumage of the Grey Dorking hens with which those Cochin-China hens are associated. We do not think that they will.

Cleaning and Feeding Canaries (*C. G. S.*).—"Have ready a good fire (and keep the kettle boiling), two basins, some very soft cloths—old 'fluffy' half-worn-out soft towels are best—a piece of common soap, and a jug of cold water. Hold the bird in the palm of the left hand, either by passing the legs between the second and third fingers, or by placing the thumb lightly across the back of the neck; partly fill one basin with warm water, and holding the bird in a favourable position begin with the tail, and with a soft rag and plenty of soap, thoroughly cleanse it: then extend the wings, and do the same to them; next the back and neck, taking care to use abundance of soap, not too much scrubbing, but a moderate pressure, always rubbing in a direction from the head to the tail. Then turn the subject on his back, and wash the breast, and finally the head and the remaining portion of the neck. Have the second basin filled with luke-warm water, and rinse the bird thoroughly. Be sure not to leave the least trace of soap, rather use two waters than rinse with that which is not quite clean. By this time the bird will be quite exhausted. There will be no fear of his attempting to fly; in fact, your chief anxiety will be whether he will ever fly again! Quickly place him in one of the soft cloths, which must previously be hung close to the fire to heat them, and as soon as possible remove all superfluous moisture by gently patting the bird, and moving it from any damp place in the towel to a drier and warmer spot, all the while sitting before the fire and holding the bird to it as near as turned-up shirt-sleeves will admit of with comfort. Dry the tail and wings as much as possible, passing every feather singly through the towel very carefully, and then, frequently changing the cloth, with a view to keeping it as warm and dry as possible, gently rub the plumage till dry. If the washing and handling seem to exhaust the bird too much, give him a rest by wrapping him up in a warm towel and placing him in the fender while you operate on a second. It is easy to have two or three in hand at the same time. I would advise you to experiment on a bird you do not value much, lest it should die under the operation. A written description is very well in its way, but you will learn more from seeing the operation performed once by an experienced hand than by any written instructions. I should have said that, when dry, put the bird in his cage, and set it in a warm spot near the fire away from draughts, and when he has plumed himself, if his appearance satisfy you, have a washing day and go through the stock. If he should die in your hands, do not wash any more, unless you have some rubbish you do not value, in which case it might be well to offer up a few on the altar of practice. Feed on the usual diet, with now and then a little hard-boiled egg.—W. A. Blaeston."

From observations taken near London during the last forty-two years, the average day temperature of the week is 43.3°; and its night temperature 30.8°. The greatest heat was 58°, on the 25th, 1827; and the lowest cold 1° below zero, on the 28th, 1860. The greatest fall of rain was 1.13 inch.

PINE APPLE CULTURE.

THERE are few persons, I should think, connected with gardening who do not know that the cultivation of the Pine Apple has not of late years increased in proportion to that of other kinds of fruits, nor even in proportion to the importance of the fruit and the demand for it at the dessert. My experience in Pine-growing is limited compared with that of many growers, but I believe the system in which I was instructed was that in general practice, and which, I was told, had been maintained with much exactness, and practised with great success, since the days of Speechley and others in the early part of the present century; nevertheless in this system I saw several things which I considered imperfections, and my opinion subsequent experience has confirmed. Likewise, I believe, those errors in culture have prevented in no small degree the more extensive cultivation of the Pine Apple

In offering a few remarks and suggestions as to the improvement and development of the culture of this esteemed fruit, I do so with a wish to be informed if my reasonings do not agree with the experience of our great growers, and if so, I may aid in obtaining for the Pine Apple the share of public notice its merits as a dessert fruit deserve.

Dispensing with much of the details of the treatment of this plant, I will at once proceed to discuss the merits or otherwise of growing large plants, which appear to have been the rage for many years. I must confess that the small fruit which, with very few exceptions, they generally produced greatly surprised and disappointed me, especially as it was often to be seen in the succession pit that a medium-sized sturdy plant yielded the largest and handsomest fruit, also several months sooner, and of course with less trouble and expense. The enormous crowns which the fruit of these large plants carried gave pretty conclusive evidence that the plants had been considerably overgrown; here, then, appeared to be an error in the treatment, and I have since seen the same results arise at other places; therefore, except in special cases when a few large fruit are in demand, I have yet to be convinced of the propriety of growing such large plants, especially as in most instances the time taken to grow and fruit a plant of large dimensions extends to years. Again, considering the atmospheric treatment necessary to the growth of such large specimens, and the amount of shading generally resorted to, I very much question if the flavour of the fruit is at all times first-class, for I believe too much shade favours the production of an abundance of juice at the expense of flavour. Another very common error is committed in the nursing pit. Here the unrooted crown or sucker often receives the treatment proper for a rooted plant—that is, too much encouragement to make foliage before sufficient roots are formed. Such treatment, if maintained throughout the growth of the plant, produces a shapeless ricketty subject, and increases the chances of overpotting and other evils. In my opinion that which would be most favourable to a more general cultivation of the Pine Apple, is the establishment of a cultural system that would produce a sturdy well-developed plant capable of bearing a fair-sized fruit fit for table within a more reasonable time. Such a system would be less expensive and more remunerative. Why should not this be done? Judging from my own experience and that made known to us by several expert cultivators, I can perceive no great difficulty to overcome. I have found the Pine capable of enduring a greater amount of rough treatment than most cultivators give it credit for, and at certain times with positive advantage instead of injury.

In the year before last I grew a dozen plants for the purpose of experiment; the sorts were one Providence, one Black Jamaica, and the rest Queens; some from crowns, and some from suckers. Not having the usual conveniences for Pine Apples, the plants were shifted about from place to place regardless of their supposed requirements, excepting that they were always placed in a moderate bottom heat, and kept near the glass until they had become dwarf sturdy plants. No notice was taken of a little sun shining on them for days together. The foliage was broad, and close down on the pot, and when the plants were about 2 feet high and as much through, I determined to fruit them; they were, therefore, taken from their growing place, and set on the stage of an intermediate house with all the sun shining upon them, but plenty of air. They remained there a fortnight, and during that time I had a small pit filled with tan, and when the tan became moderately warm the Pines were plunged into it. They were kept warmer at the top than before, and very soon every one of them showed fruit. The atmosphere was always kept dry, especially in the flowering period, and they had sun enough to render their foliage quite brown, and always plenty of air, but very little water at any time. With the exception of the Providence and Black Jamaica, all ripened their fruit in twelve months, and three of them weighed 9½ lbs.

I am aware that there is nothing extraordinary in the above experiment, or more than others have accomplished, but I state it to show what results may be achieved with a plant that has for many years been cultivated with such tender care; and if I were called upon to produce a quantity of this fruit annually, I should certainly have recourse to something like the same sort of treatment.

I have for a long time thought that the Pine has been cultivated with too much care at certain stages of its growth, and that the old system which has been adhered to with such pertinacity for so many years has been far too expensive for many to embark in Pine cultivation; no doubt, also, the large annual importation of foreign fruit of such good flavour has done much to check the cultivation of home-grown fruit. Those, however, who have the idea of an improved system of cultivation will do well to remember that there is the foreign fruit to compete with, and in point of flavour we can successfully do so; therefore no treatment, however good, will be

worthy of adoption if it in the least deteriorate this important quality.—Thomas Record.

FORCING PLANTS.—No. 6.

Convallaria majalis (Lily of the Valley).—This old favourite is in most places greatly in demand both for decorative purposes and cut flowers. It may be forced in pots, pans, boxes, and in a variety of ways, but for decorative purposes pots or pans are most suitable; whilst for lifting when in bloom for filling vases, along with other plants, it is best forced in narrow shallow boxes.

The plants most suitable are those which have been grown in beds in the open ground for three years, in the first place planted about 6 inches apart in rows 1 foot apart, each cluster having from three to half a dozen crowns. These beds are best made in November, a rich, sandy, fibrous loam being most suitable. The situation should be shaded, but not by trees, the shade of a wall being ample. A north, north-west, or north-east border is the best. The ground should be deeply dug, mixing with it some leaf soil, but no manure. In spring stir the surface lightly, just when the leaves are pushing, and top-dress with an inch thick of light rich compost; rotten leaves, old cow dung, and sandy fibrous loam in equal parts make a very good top-dressing. This may be applied every spring, nothing further being required than keeping them clear of weeds and watering abundantly in dry weather. By the third year they will be fine clumps, each as large as they need be for a pot, and many sufficient to fill a tolerably large pan, whilst the smallest will be suitable for boxes, to be transferred to vases, &c., when in flower.

For blooming in December the roots ought to be potted early in November, or if required to flower early in December they would be better, and indeed ought to be, potted at the end of October. In potting, good drainage is required for the pots or pans, as the plants need very liberal supplies of water, also a light sandy soil, and pots sufficiently large to hold the roots but no more. After potting give a gentle watering, and set the pots on a hard floor in a house with a temperature from fire heat of about 45°. If the floor be moist, all the better, and a position under the stage, if not much liable to drip, will do as well as any other. Cover with cocoa-nut refuse over the pots to the extent of 4 or 6 inches, if it is desired to have flowers with long stalks, and they will not require any further attention until the leaves are appearing through the refuse; then remove them, and you will find the flower stems little short of the length of the leaves, and the flower buds only need bringing out. To do this place the pots in a light airy situation about 1 foot from the glass, shading from 10 A.M. to 3 P.M. for about a week if the weather be bright, but if it is dull the shading will not be necessary. In a few days the foliage, acted upon by the light, will become green, and the flowers will expand on a good stalk, and be anything but like those forced from the first in light, with the flowers on dumpy stems and smothered by the foliage. A temperature of from 45° to 50°, and not exceeding 55° from fire heat, is sufficient. Five to six weeks are needed to have the plants in bloom, so that fresh lots of plants should be introduced at fortnightly intervals to keep up a good succession of bloom. For covering the pots sawdust, spent hops, or tan will answer, but cocoa-nut fibre is best. Inverted pots, however, answer nearly as well as covering the pots with cocoa-nut fibre if kept on until the spikes are 5 or 6 inches high, and then removed. Up to that time a shady position will do, but after the removal of the inverted pot the pots should be placed near the glass, shading for a few hours in the middle of the day if the weather be bright, but only for a few days. As the pots are not plunged, they will lose moisture by evaporation, therefore water must be supplied to the plants as required; after growth commences they must not on any account be allowed to become dry. The water used should be of the same temperature as that of the house—a few degrees higher rather than less.

If the plants are to be removed in flower to vases, baskets, &c., and in small patches or individual plants, I select those of the required size singly, or in twos, threes, or any number up to half a dozen. Every crown should be thick, plump, and round, it being of little use wasting time and room with those which are long, thin, and sharp-pointed, as they will not flower, or very weakly. These pieces should have as much root and soil as possible preserved along with them, and the root portion should be neatly wrapped in moss, adding soil if there be but little adhering to the roots. To keep the plants distinct, and to permit of their being transferred when in bloom with as little injury as practicable, secure the moss with matting, but not very tightly. Place them in boxes or pans closely together, and fill in the interstices with fine soil; or cocoa-nut fibre refuse will answer quite as well. They should be placed so deeply as to admit of an inch-covering of moss, which will tend to preserve a more uniform degree of moisture, and should be covered with an inverted box or pan, stopping up the holes, if any, to keep all dark. A good watering ought to be given before covering with the moss. The boxes or pans should be placed on a gentle hotbed in a house with a temperature not exceeding 50° from fire heat, but 45° will be better for a period of two or three weeks at the commencement. The soil must be kept moist, and tepid water only used. When the flower stems are from 4 to 6 inches high remove the inverted boxes or pans, and place the pots near the light; the plants will come into fine bloom in a few days, and as each root is enveloped in moss they may be transferred to vases or wherever wanted.

By either of the above plans these desirable flowers may be obtained at Christmas, or earlier, as well as throughout the winter. Those flowered early will be of little value afterwards; but those not flowering before February or March, may, after flowering, be hardened-off in a frame, and be planted-out when danger from frost is past; but a better plan is to keep them turned out in a shady border, after hardening-off as above during the summer, and in November take them up, shake away most of the old soil, and plant in bunches in a bed in rows as mentioned at the commencement of this article, top-dressing in spring, and watering in dry weather in summer. In three years they will be fine bunches fit for any purpose.

Spiræa japonica is a hardy deciduous herbaceous plant, very fine for forcing. The foliage is elegant, and bright dark green. In general outline it very much resembles the pretty Fern Anemidictyon phyllitidis, but is more dwarf and branched, and the flower stem is erect, and bears a profusion of small white flowers, very pretty; it is one of the most desirable of plants for the dinner-table and decorative purposes of all kinds, and for cut flowers is indispensable. Everybody should grow it.

It is increased by division, November being the best time to divide the plants into as many parts as there are crowns, preserving to each a good portion of root. Plant them in a bed of rich friable loam, enriched with leaf soil, and deeply dug. The divisions may be put in in lines 1 foot apart, and 6 inches from each other in the lines, not covering the crowns more deeply than an inch with soil. In spring mulch the bed with an inch thick of rich compost, such as equal parts of turfy loam made fine, leaf mould, and old cow dung or very rotten manure. Keep the plants clear of weeds, and water them copiously during dry weather in summer. The following and succeeding spring stir the surface of the beds, and mulch with rich compost as in the previous year. In three years they will be fine plants. A slightly shaded situation is most suitable.

If the plants are required to bloom at Christmas, they should be potted in the beginning of November, employing pots just sufficiently large to hold the roots. Good drainage should be given, and the soil may consist of sandy loam two parts, and one part leaf mould. After potting water gently, and set the pots on ashes in a frame if the plants are not wanted for immediate forcing, plunging the pots in, and covering them with, about an inch of spent tan, sawdust, or cocoa-nut refuse, which last is best. From the frame they may be taken into the forcing house at fortnightly or more distant intervals from November to March. If required to bloom at Christmas, the plants, on being potted early in November, should be placed in the forcing house at once, setting the pots on the floor, and covering them about an inch thick with any kind of loose material. The temperature from fire heat should not exceed 45° for the first fortnight, and when the leaves are appearing through the plunging material remove the pots, and place them in a position near the glass, so as to keep the plants dwarf, for if set at a considerable distance from it they will be drawn up tall and weakly. An abundance of water and a moderate amount of air are required, the temperature being raised to 50°, and not exceeding 55° from fire heat. The plants bloom in about six weeks after being introduced into heat. After flowering they should be kept under glass until they are well hardened-off, and danger from frost is past; then turn them out of the pots in a shady border. In November they may be divided, and with the treatment before given they will be quite fit to be forced again in two or three years.

Dielytra spectabilis is, perhaps, the most brilliant of spring-flowering deciduous herbaceous plants. It is too well

known to require description. It requires a rich light soil. One-half loam, one-fourth leaf soil, and one-fourth old cow dung, will grow it well. It is increased by division of the crown early in spring, and by cuttings of the shoots in summer, which strike freely in sandy soil in a gentle heat.

For forcing good strong roots should be taken up in October, and potted, and though they may be forced at once, I prefer growing them in pots a year previous to forcing, putting them in good-sized pots or such as they will go into without cramping, and I plunge the pots to the rim in ashes in a sheltered sunny situation. Cover the crowns with any kind of loose material, as leaf soil, and they will be safe from frost. The following summer they are well supplied with water whilst in active growth. When the leaves turn yellow lift the pots, and transfer the plants to larger pots, loosening the sides of the balls with a pointed piece of wood, removing as much of the old soil as far as is practicable without injury to the fleshy roots. The shift should be liberal. Set the pots on ashes, and cover them as well with ashes to the depth of about 3 inches. They may then be taken into the forcing house as required.

When placed in the forcing house they should have a temperature of 40° at night for a fortnight, then raise it to 45°, and progressively with growth to 50°, which is a sufficient temperature from fire heat. They should have a light and airy position. Forcing for blooming at Christmas should be commenced the second week in November, and plants introduced at fortnightly intervals to March will keep up a succession of bloom till April. Water should be sparingly given until the plants are in free growth, then water copiously.

After flowering continue the plants under glass, hardening them well off, and then plunge the pots out of doors in a warm situation. The plants should be potted when the foliage decays, and to prevent second growth they should be kept dry, otherwise early-forced plants not unfrequently start into growth in summer in moist weather and flower again in autumn. They may be forced the second year, and successively. Plants not started before February will be as good for forcing in the second year as in the first; indeed, I have had them increasing annually in size and beauty for many years, when merely brought forward in a cool house. Plants 3 feet high and 6 feet in diameter, may be grown in pots. I have found growth encouraged by weak liquid manure given alternately with pure water when the plants were growing freely.

Dielytra spectabilis flore-albo with white flowers, makes a charming companion to the pink-flowered form.—G. Abbey.

DOYENNÉ DU COMICE PEAR—CORDON TRAINING.

The very attractive description given in a recent number of "our Journal" of that most delicious Pear Doyenné du Comice will, no doubt, incline some of your readers to become purchasers of such an excellent variety. I have cultivated this fruit in my garden, situated amongst the hills of Yorkshire, for eight years, and some account of my failures and successes may be useful to others.

In the autumn of 1861 I asked Mr. Rivers to send me, amongst other things, a dwarf-trained plant of Doyenné du Comice on the Quince stock. When it arrived it proved to be grafted on the Pear, and Mr. Rivers accounted for this by saying that he had not been able to persuade this Pear to succeed well on the Quince. This plant was placed against a south stone wall, and received every attention. It was from time to time lifted and root-pruned, yet not so severely as unduly to check its vigour. At last, in 1867, its one fruit bud flowered, and set one fruit. This precious specimen grew to be about 5 ozs. in weight, and ripened off well.

The summer and autumn of 1867 were cold, wet, and cloudy, and most unfavourable to the ripening of fruit, nevertheless Doyenné du Comice did not seem to be injuriously affected, but ripened well its fruit and its wood, and sustained the following winter a temperature of 10° below zero. So I think this variety may be considered to be not only very hardy, but also suitable for cool climates. In 1868 this tree bore six fruit, the largest of which barely reached 6 ozs.; it proved to be melting, juicy, watery, flavourless.

In 1864 I succeeded in obtaining this Pear budded on the Quince, and I planted it against a south brick wall, and it made stout, satisfactory growth year by year. In 1867 I purchased a single cordon on the Quince, and placed it by the side of the tree purchased in 1864. Both these trees on the Quince bore fruit in 1868. The 1864 tree gave me nine large Pears of nearly equal size, the weight of the largest being 11¼ ozs. The single cordon, though it had only been planted during the previous autumn, carried two large fruit, each weighing 10½ ozs. How good these Pears were!—better than Conseiller de la Cour, better than Marie Louise, better than Winter Nelis, better and more Peach-like than any Pear I have ever tasted. Strange that while the fruit from the Quince stocks should be so good, those from the Pear stock should be so inferior. As these two trees on the Quince did not in the autumn form any fruit buds, they were both forked most carefully out of the ground, slightly root-pruned, and then replanted with fresh soil and a liberal supply of manure. The result is that last summer they made a robust healthy growth about 18 inches in length, and have covered themselves with fruit spurs.

This year Doyenné du Comice on the Pear set six fruit; three of these fell off in August and September, though the tree was well mulched, and never suffered from dryness, was in perfect health, and had not been disturbed for two years. The three remaining fruit barely attained the weight of 7 ozs., and were watery and flavourless. As this tree has a few fruit spurs on it, I shall give it one more trial. In a neighbouring garden a tree of Doyenné du Comice on the Pear stock has grown there for nine years, and the gardener has not seen on it so much as a single flower. From this I conclude that the Doyenné du Comice is a very shy bearer on the Pear stock, and will not give fruit of large size and true to character until it has reached a mature age. Who would think of waiting all these years, when, by buying a single cordon on the Quince, fine fruit may be gathered within the space of twelve months? On the Quince stock it is evidently quite sufficiently fruitful for its health.

If anyone has recently procured this tree on the Pear stock, I recommend him to throw it away at once—this course will save endless trouble and annoyance—and buy it budded on the Quince, dwarf, and trained upright exactly like a five-pronged digging fork. Such a tree as this will occupy scarcely a yard of wall in length, and will never require any more room. In three years it will bear a nice crop. In eight years it should reach the top of a 12-feet wall, and produce annually from fifty to sixty fruit. This is quite a moderate estimate, as several of my trees so trained yield annually eighty Pears, or even more. This is the most profitable, and therefore the best mode of training all fruit trees. They can all be trained upright, and are more healthy, and more fruitful, than when trained horizontally. A fruit wall should be covered from one end to the other, and from the bottom to the top, with fruit-bearing branches 9 inches apart. Each Pear cordon should bear twenty fruit annually. Four hundred and fifty fruit on 6 yards of wall—what an enormous produce! and that obtained here year by year, without exhausting the trees. In 1867, my Pear trees gave me 1000 fruit; in 1868, 1200; in 1869, 1300, all fine, free from cracks, thus showing a progressive increase, and no exhaustion.

Here Pears, Plums, Apples, Cherries, and Peaches, are trained upright, as I have described. All now have reached the top of a 12-feet wall, and all bear profusely. So successful has this upright mode of training proved to be, that several of the gardeners around me have heartily adopted it.

Then, again, no other plan of training is so economical of space. The entire wall is covered; no vacant places, so commonly to be seen where trees are trained on the fan or horizontal method. Then, how soon the wall is covered! It requires fifteen years for a tree trained after Seymour's fan-system to reach the top of a 12-feet wall. Eight or nine years will suffice to cover the same wall with upright-trained trees. Who would wait for fifteen years for that which can be done better in nine years?—C. J. M.

NOTES ON ROSES.

The experience of Rose-growers varies remarkably, and, consequently, each may mention facts new and, therefore, interesting to the brotherhood. Now, my ground, like Mr. Kent's, as stated by him October 7th, is light, and yet many little items that he mentions I have to say the reverse to. Charles Lefebvre and Marie Baumann, which he instances as models of constancy, I find very uncertain; on the other hand, Alfred Colomb, John Hopper, and Pierre Notting, which he mentions as behaving badly with him this year, have been about my best. Maurice Bernardin has with me a dull streaked blossom.

Beauty of Waltham is of a dull cherry colour, very loose in texture. These two Mr. Kent puts among his most brilliant crimson scarlets. Lord Macaulay succeeds neither with me nor with anyone that I know of in this neighbourhood. Its blossoms are small, and of a muddy plum colour, and the constitution of the plant wretched. Exposition de Brie has not had a single well-opened blossom, while Dr. Andry, which Mr. Kent describes as dull, is with me almost the most brilliant-coloured Rose I have. Antoine Ducher is first-rate with me in all respects; Thorin the same. Charles Rouillard has bloomed most profusely; the blossom most regular in shape, but the colour, a poor lilac, is unpleasing to me.—Q. Q.

MELONS ON RIDGES.

It may interest amateur gardeners to know, that although the summer was very backward this year, I have again to record my success in growing the Melon Achaspesnorricher (scarlet flesh), out of doors on a ridge, and although, owing to the late spring frosts, I was unable to turn the plants out so early as last year, still I grew some excellent fruit, the largest weighing 6¼ lbs. The old Beechwood Melon (green flesh) also, under the same treatment succeeded well and produced even better-flavoured fruit than the same sort grown in a frame; though small, weighing but 2½ lbs., yet they were handsome, and, as I before remarked, of exceedingly good flavour; in fact, so good that some of my friends intend in future to rely on out-door culture for this part of the year.

I find the beds should slope towards the south. The crowns of the plants should have a pot placed over them to protect them from the wet and too much sun, and the fruit should rest on slate, otherwise the part touching the ground is apt to rot.

Planters should be particular that the plants receive no check from putting them out too early, or taking them from a very warm frame. The larger the hand-lights the young plants when placed in the bed are covered with the better. In my own case, those only covered with small bell-glasses when first planted produced the smallest fruit, while those started under a ground vinery grew the largest and best, though all were planted in the same soil and on the same day.—Harrison Weir, *Weirleigh, Kent.*

GOOD CIDER APPLES.

[At the request of several correspondents we have inquired for the names of these, and the following is a reply we have obtained.—Eds.]

It is difficult to obtain the names of the best cider Apples, for men who understand the art of making excellent cider are very often ignorant of the names of the trees in their orchard from the fruit of which it is made. One of my neighbours, however, of whom I bought a hogshead of first-rate cider in the spring of this year, tells me that he makes his best of Royal Wilding, the Norman, and Skyrme's Kernel, all mixed together.

The Royal Wilding is of good quality, yielding better than "family" drink, but not quite equal to the others. The Norman is a vigorous grower, an important point in a light soil, and soon comes into bearing. Several of the best cider Apples seem, like the old Golden Pippin and the Ribston, to have worn-out their constitution. Such are the highly-valued Skyrme's Kernel, of which even newly-grafted trees are feeble and sickly, and the famous Fox Whelp, which yields a dry cider of considerable strength, not long remaining luscious as some ciders do, but reaching maturity early, and fit to drink in a few months after it is made. This Apple is still grown in Herefordshire, and I bought a good cask of its cider this year. The White and the Yellow Styre produce cider which has been known to sell at 2*s.* 6*d.* a-gallon—a high price in this part of the world—but they are somewhat shy bearers. In Mr. Knight's "Pomona Herefordiensis" it is mentioned that the Brandy Apple, now chiefly known as a dessert fruit, used, as well as the Golden Pippin, to be extensively grown as a cider Apple, and that it takes its name from the potency of the beverage produced from it. I have heard of its being still used for this purpose, and also of its continued strength. The Herefordshire Red-streak is another well-known Apple, but I am not sure of its constitution. Among the best is the Black Kington or Kingston, the cider of which from a farm in this neighbourhood gained the prize last year both at Hereford and at Gloucester.

In Somersetshire I have heard that no fruit is more highly esteemed than the Underleaf, which takes its name from the peculiar way in which the fruit is concealed by the foliage.

The best cider in this county is made on clay lands, and on a light soil the vigorous and large-leaved kinds, such as the Blenheim Pippin, among dessert fruit, are the most successful. It will be well for your correspondent to bear in mind the quality of his soil, and adapt his trees to it.

"The best sorts of fruit are the Royal Wilding, Fox Whelp, White Bush Normandy, Yellow Styre, Handsome Mandy, and Skyrme's Kernel."—(*Quotation from a letter of a prizetaker in* 1859.)

A correspondent says he has only two kinds of Apples from which he has succeeded in making the best cider—that is, cider sufficiently good and rich for bottling, and these are the Devonshire Red-streak and the Kingston Black Apple, the latter of which makes much the richest of any Apple that he has ever known, though not, perhaps, equal in strength to the Devonshire Red-streak, or some other kinds; but he prefers a mixture of those Apples to make nice and palatable cider; though it is more difficult to manage, being more liable to fret and become of inferior quality when mixed than when made separately. He has exhibited cider made from the Kingston on two occasions at Hereford, and on three at Gloucester (which are the only times he has exhibited), and has received four first prizes for it, two of which were in October and November last; therefore, he thinks that he is justified in supposing there is no Apple in Herefordshire or Gloucestershire which surpasses it.—Wyeside.

BOILERS—HEATING THEM AND BY THEM.

I expected to have my views about heating boilers from above controverted, as I was well aware that they are contrary to preconceived notions; but Mr. Woolfield ought to know that contradiction is not argument, and it is no compliment to say I did not reflect.

An oven is heated much the same as water in a boiler, by the heated particles of air rising, and the top of an oven will always be hotter than the bottom. It is true that water is boiled by convection; but it is a very different thing boiling water in a kettle over the fire to boiling water in a close boiler like a saddle boiler, where there is a flow-pipe to carry the water off when heated, the cold water being supplied by the return; and when once the fire is well lighted and begins to act upon the water, a constant current or circulation of water is kept up. The relative value of heating surfaces which Mr. Woolfield quotes is very arbitrary, and refers more to boilers set for generating steam; but even were I to allow (which I do not), that the relative values of heating surfaces are such as he quotes from Molesworth's "Engineers' Pocket-book," yet even then I can prove that the flame playing over the top of a saddle boiler has much more relative value than he is inclined to admit. The top of a saddle boiler is convex, and therefore varies from vertical to horizontal. Take the average of the curve, the value of the vertical surface being 0.50, and of the horizontal 0.00, the value of the heating surface of the whole curve will average 0.25; and as in most saddle boilers the exterior curve is about one-fourth larger in point of surface than the interior curve, this will raise the value to 0.343 as the average value of the whole heating surface of the upper part of the boiler. And, as in the same way, the interior upper surface of the boiler is concave, the value of the heating surface of the interior will vary according to Mr. Woolfield's laws from 0.50 to 1.00, or, taking the average, it will be 0.75; so that, even according to the data given by Mr. Woolfield, the exterior upper surface bears no small relative value to the interior—*i. e.*, 0.343 to 0.75. If Mr. Woolfield denies the accuracy of this he will have to deny there is any heat given to the upper surface of pipes when introduced into boilers, as in the case of one of Ormson's new patent tubular boilers, as see the right-hand figure in the advertisement which occurs every week in "our Journal," or, again, in Shanks's combined saddle and tubular. It is, however, absurd to give 0.00 as the value of horizontal surfaces under flame; because, if this were true, and these pipes, as in the two instances I have quoted, were square instead of round, the upper one-fourth would be of no use; besides which, the relative value of 0.00 to 1.00 is infinite and indefinite. The value of horizontal surfaces under flame must be definite—that is to say, it must bear some relative proportion, and I have yet to be convinced that it does not bear a much greater value than what is usually allowed; because, as

I think I before stated, though I have not the paper by me, as there is a constant circulation of heated water in a saddle boiler, the water which comes in from the return-pipe, having been cooled as it has gone through the pipes in the houses, comes in contact first of all with the heated sides of the boiler, then rises to the curved portion, and strikes against the upper surface. If this upper surface were not heated by the current of flame playing over it, it would either repel the water or help to cool it; but as the heated air from the fire is of necessity hotter than the water in the boiler, it assists to heat the water still more, and so helps the flow; and as the flame passing over the surface of the boiler also plays round the flow-pipe, which it surrounds, it adds additional heat at a most important point.

Mr. Woolfield corrects me in another point about the diameter of the feed-pipe. I am aware he is right about the pressure of water depending on the height of the column of water in the pipe, but it is also true that when hydraulic pressure is applied to water in a small pipe it is greater than when applied to a large one. I may have overrated it, but as the feed-pipe has to relieve the boiler of the pressure caused by expansion in boiling, the larger the size of the feed-pipe the more easily the pressure is relieved. Many leaks in joints are owing to a small feed-pipe, and it will always be noticed when a joint does leak it leaks far more when the water in the boiler is very hot.

And now I must make a few remarks upon Mr. Woolfield's paper, in which he gives directions for the quantity of piping required to heat a house a certain number of degrees of heat above the temperature of the atmosphere. He tells us the quantity of air to be warmed per minute is 1¼ cubic foot for each foot superficial of glass the house contains—to be warmed how much? The radiation of heat from a house does not depend so much on the difference of temperature between the external and internal air as on the force and the direction of the wind, as regards the surface of glass exposed. This is such a variable quantity that no general rules can be laid down. One night two weeks ago, with the thermometer at 25°, a small house cooled so rapidly that, although there is a flow and return pipe at the back of the house, it was found necessary to light a fire in a flue which used to heat the house previously to the hot-water pipes being put into it, and although a good fire was kept up in the furnace the thermometer inside fell to 40°. The next night the external temperature was as low as 19°, but the temperature in the house never fell below 45° without the flue being used at all. In reckoning the radiating powers of glass, the angle of the roof has also to be considered.

Again, I do not agree that two rows of 2-inch pipes are superior in economy to one 4-inch pipe, because the water in the 2-inch pipes cools down twice as quickly, and, therefore, though it may require less fuel in the first instance to heat them, it requires much more afterwards to keep the heat up, and for nightwork this is the most important point.

Again, he gives 125°, a fixed quantity, as the excess of temperature of the pipe above the surrounding air. This, I need hardly say, will vary with the difference of distance from the fire, and with the fire itself. Again, he gives 222 as the number of feet of air raised 1° per minute by 1 foot of 4-inch pipe. This, also, which he gives as a fixed quantity, must vary according to the heat and also the position of the pipe, and the radiating power of the external atmosphere. In fact, I think I may fairly say that all the data which he gives as fixed rules for finding out the necessary quantity of pipes are variable and uncertain.

One square foot of boiler for every 50 feet of pipe may be a very good rule; but on this head, again, doctors differ, as Mr. Weeks, in his pamphlet on greenhouses, &c., gives 25 feet for 200, 250 feet for 4000, 400 feet for 10,000. I am aware that in this Mr. Weeks calculates every surface of any sort in the tubular boilers, and I also think there are great discrepancies, especially in the last two items, where 150 feet additional surface has to heat 6000 additional feet of pipes, whereas a boiler with 150 feet of heating surface in the same list is calculated to heat 1500. I have only quoted this to show there is great difference of opinion on this head, and I am now heating thoroughly and efficiently nearly 450 feet of piping with a boiler which, according to Mr. Woolfield's method of calculation, would only be sufficient for about 300 feet; but then I calculate the exterior and upper surface as an additional source of heat, which Mr. Woolfield does not.

What Mr. Woolfield states as to unnecessary depressions and rapid curves cannot be too strongly insisted upon, and that is another reason in favour of 4-inch pipes over 2-inch, as there is less friction, and water flows more freely. Let me again repeat that the position of pipes, so as to allow free radiation, is most important; and if persons do not believe in radiation of heat downwards, let them place some pots 2 feet below hot-water pipes and see how rapidly they will dry; or, again, fill a bottle with water, and put it flat underneath a grate, and another bottle of an equal size at the same distance in front of the fire, and see which will be heated first. I would also impress on your readers that the laws for boilers for generating steam, for boilers for the circulation of hot water, and ordinary boilers, such as those set at the side of a kitchen fire, are not the same.—C. P. Peach.

APPLICATION OF MANURES.

I must say I was much surprised at seeing the following remark, "When Professor Voelcker speaks of no fear of waste if the soil contains clay, he only refers to what is washed into the soil by the rains." The whole tenor of his argument goes to show that little or no loss can be sustained by spreading manure, whilst an enormous loss is usually sustained by rotting manure in heaps exposed to rain. He very properly says "if the soil contains clay," because the soluble ingredients would wash through some poor sandy soils if put on too long before the crop intended to be benefited were sown. From the editorial remarks it would also appear that there was a difference of opinion as to the propriety of burying manure as soon as convenient. Now I think this is hardly a fair inference. All I contend for is that manure takes so little harm from sun and wind when spread on the ground, that it is foolish to keep it in heaps when rotten manure is not a necessity, as in the case of sandy land. Then, again, I cannot agree with our Editors "that the guano latitudes are characterised by a singular absence of rain." From what I have gathered of those regions rain very seldom falls there, and those places like Peru, where the least rain falls, send us guano which is richest in salts of ammonia. From this I gather that if there were no moisture there would be no loss. With regard to the value of any carbonic acid which could be lost by spread manure, I should say it would be about equal in value to that given off by the "old stick."

There is one point in the editorial remarks which appears worthy of consideration—"Urine rapidly decomposes in the litter of a stable." No doubt it does when the stable is warm enough to induce fermentation, and when each fresh supply of urine comes in contact with urine undergoing change. How long will a sound Apple remain sound when in contact with a rotten one? But who ever smelt ammonia very strong in a cold clean stable? and where it is most abundant how little is necessary to produce the effect perceived. Can anyone contend that urine exposed to sun and wind is under the same conditions as urine in a damp, warm, and close stable? I keep eight horses myself, but if my stables smelt strongly of ammonia I know some one would hear of it; nor do my men use gypsum or anything else to fix the ammonia. Thinking that Professor Voelcker was most likely to know what he intended to teach, I sent him the Journal of December 2nd, and asked him to be kind enough to state whether the inference drawn from his essay was correct, and he very courteously sent me the following reply, which, as far as I am concerned, closes the matter. The subject to me is one of great interest, because it is of great importance to me personally. Paying as I do some hundreds a-year for manure, besides what I make on my own farm, it would not be pleasant to think a good deal of it had been wasted; still, it would be much worse to pursue such a course in error.—J. R. Pearson, *Chilwell, Notts.*

DR. VOELCKER'S LETTER.

"In reply to your note, I beg to say that the Editors of The Journal of Horticulture do not give a correct explanation of my decided opinion that farmyard manure spread out on the field loses no fertilising matter by exposure to wind and sun. My opinion rests on experiment, and not on mere speculation; and the practical direction which I always give to my farming friends is, Take your dung on the field *at once*, and wait till the land is in a fit state to be ploughed up. I have noticed over and over the mischief which is done by ploughing in manure in wet weather when the soil was not in a fit condition to be worked by men or beasts. In clay soils, especially, more harm is done by the plough and horses' feet than good by the manure. It is, therefore, most desirable that agriculturists

and gardeners should know that wind and sun do not dissipate any fertilising matter when dung is spread in the field. The whole amount of free ammonia, or rather carbonate of ammonia, in fresh farmyard manure amounts, as shown in one of my experiments, to only 0.189 of a per cent.; and it does not follow as a matter of course that even this small fraction of a per cent. of ammonia will find its way into the air, for it is far more likely that the soil will at once absorb it when the manure is spread on the field. Allow me to direct your attention to an experiment which you will find recorded in my paper on farmyard manure in the Royal Agricultural Society's Journal. On the 3rd of November, 1854, I put up a heap of dung weighing 2838 lbs. In this quantity the total amount of nitrogen present in any condition was 18.23 lbs. On the 30th of April, 1855, I weighed again the heap, which had been exposed to the air all that time, and found in it the total amount of nitrogen 18.14, or almost exactly the same as in the November of the preceding year, showing that no ammonia whatever was lost by exposure to the air. Yours faithfully—Augustus Voelcker."

[The above confirms our opinion. By leaving manure on the surface of the ground exposed for a length of time to the sun and wind it can gain nothing, and certainly does lose some of its fertilising constituents. Mr. Pearson now admits this, although "so little." Let it be granted that the nitrogen it loses is in all instances as small as that shown by Dr. Voelcker's experiment, why should that be lost needlessly? It amounts to much where hundreds of tons of manure are used. We quite agree that it is bad culture to plough or dig in manure into a heavy soil whilst it is wet, and we also agree with Mr. Pearson that it is worse practice to leave manure in heaps than to spread it. He says that is all he contends for. So the controversy closes.—Eds.]

CORDON APPLE TREES AND RABBITS.

A few years ago, either from your columns or Mr. Rivers's "Miniature Fruit Garden," I learnt how to plant and train these trees, and I should have had some success had it not been for those sad pests to gardens—rabbits. I seldom or never see one, but my neighbours tell me that if there is a rabbit within a mile he will smell out a young Apple tree, so will a hare. The consequence of this is, that my cordon trees are nibbled so as to bring on canker and make them objects of disgust, for a cankered Apple tree is an ugly thing. I have tried the remedies often suggested in your columns, such as painting the trees with lime, and soot, and milk, but these washes soon vanish in winter owing to the alternations of frost and thaw (I once tried coal tar, and once only, for it destroyed my trees), and then Mr. Rabbit seems to rejoice at his meal on clean bark, and will ruin a dozen trees in a night.

Mr. Robinson recommends with great enthusiasm cordon Apple trees for market gardens. If he could spend but one season in an unwalled market garden of his own planted with cordon Apple trees, he would be a wiser and, perhaps, a sadder man. There is no difficulty in cultivating cordon Apple trees in walled gardens, but in unwalled gardens even as near London as Fulham, rabbits are always doing mischief. I have within the last year or two found what is in my experience a new method of doing mischief by these vermin; they used to gnaw off the bark, but they now prefer a daintier dish, and eat out all the blossom buds before they commence to gnaw the bark.

My gardener recommends thorns from the hedges bound to the trees, or straw tied to their stems, in both cases not agreeable nor adapted for large gardens.—Inquirer.

ENTOMOLOGICAL SOCIETY'S MEETING.

The December meeting of this Society was held on the 6th inst., the President, Mr. H. W. Bates, being in the chair. The Baron von Holten, a Russian entomologist, was present as a visitor. Some important entomological works, published by the Swedish Government, were on the table. Mr. Frederick Smith exhibited on the part of Mr. Lord the case made by the caterpillar of a species of Oiketicus, taken by him on Mount Sinai, several miles distant from any tree or bush, the only plants of which the case could have been made being a kind of wild Sage; also the cells of a wild Bee of the genus Halictus, the cells being formed in a large cluster at the foot of a tubular tunnel 12 inches deep, the mouth of which was defended by a trumpet-shaped tube of sand.

Professor Westwood exhibited drawings and specimens, and described a number of remarkable new exotic species of Pselaphidæ and Chalcididæ. Mr. Jenner Weir exhibited specimens of Heliothis armigera, the caterpillar of which had devoured the interior of a quantity of the fruit of Tomatoes imported from Portugal. Mr. Albert Muller exhibited photographs of a monstrous specimen of Pterostichus Prevostii Dejeam, captured near Neufchatel, in Switzerland, having two supplemental legs affixed to one of the ordinary hind legs. Mr. MacLachlan read a note on the species of the curious genus Borens, with the view of proving that the B. Westwoodii of Hagen had no claim to be considered as an English insect.

Dr. Wallace communicated a notice on the recent results obtained in the cultivation of the different new exotic species of Silkworms in this country, with directions for the most effectual rearing of each.

The Secretary read a notice by Mr. Sidebottom on the modifications of colour in caterpillars, chrysalids, and perfect insects, reared under different coloured glass, which led to an extended discussion, in which Mr. Wallace suggested the advisability of rearing the insects under reflected rather than under transmitted light, by placing them in boxes lined with different-coloured papers, adding that the employment of different-coloured glasses in plant houses had for its object the modification of the temperature, and not of the colours of the plants.

ROYAL HORTICULTURAL SOCIETY.

December 21st.

Fruit Committee.—G. F. Wilson, Esq., F.R.S., in the chair. The Rev. George Kemp, Sevenoaks, offered two prizes, one of £3 for the best, and the other of £2 for the second best winter dessert of Apples and Pears, three dishes of each. There were six competitors. Mr. Tillery, of Welbeck, sent Calville Blanche, Blenheim Pippin, and Cox's Orange Pippin Apples; Van Mons Léon Leclerc, Doyenné du Comice, and Winter Nelis Pears. Mr. Earley, of Digswell, sent Joséphine de Malines, Winter Nelis, and Chaumontel Pears; and Ribston Pippin, Cockle Pippin, and King of the Pippins Apples. Mr. Gilbert, of Burghley House, sent of Apples, Blenheim Pippin, Ribston Pippin, and Lord Burghley; and of Pears, Beurré Langelier, Passe Colmar, and Beurré de Rance. Mr. Sidney Ford, of Leonardslee, had of Pears, Knight's Monarch, Duchesse d'Angoulême and Joséphine de Malines; and of Apples, Ribston Pippin, Blenheim Pippin, and Red Pearmain. Mr. Garland, of Killerton, Devon, sent Golden Pippin, Nonpareil, and Ross Nonpareil Apples; and Winter Nelis, Glou Morçeau, and Bergamotte Esperen Pears. Of the collections, all of which were good, the best both in appearance and flavour was undoubtedly that sent by Mr. Garland, to which the first prize was awarded, and the next that of Mr. Ford, which received the second prize. The Knight's Monarch of Mr. Ford were unusually fine.

Mr. Cramont, gardener to Edward Backhouse, Esq., Ashburne, Sunderland, sent a seedling Grape, somewhat of the character of White Tokay, a good, long, and showy bunch, but the berries possessed no flavour; if they ever did it must have passed, the fruit having evidently been ripened for some time.

Mr. Thomson, Dalkeith, sent a bunch of White Lady Downe's Grape, which not being ripe, and the flavour undeveloped, a wish was expressed that it be sent again in March. It was considered by the Committee to be a promising variety. Mr. A. McLeod, gardener to Mrs. Holt, Sudbury House, Harrow, sent two large bunches of Gros Guillaume, called Barbarossa. Mr. Tillery, of Welbeck, sent dishes of Beurré Superfin and Forelle, grown on a trellis of an arcade. Both were of very good flavour, particularly the Beurré Superfin, Forelle being rather watery. These were equal in flavour, if not superior, to all others exhibited. He also sent a seedling Pear raised from the Chaumontel crossed with Gansel's Bergamot, but the Committee could not observe any difference between it and the Chaumontel.

Mrs. Blackett Ord, Whitfield Hall, Haydon Bridge, Cumberland, sent fruit of Farmer's Seedling Apple, which is a good kitchen Apple. A dish of very fine Tangierene Oranges came from Lady Dorothy Nevill, Dangstein. In size and flavour they were superior to imported fruit, and a special certificate was awarded to them.

Mr. Dancer, of Little Sutton, Chiswick, sent a dish of Cox's Orange Pippin, and Beurré d'Aremberg Pear, the former superior in flavour to all the Apples exhibited at this meeting, and a special certificate was awarded to them. Mr. Hepper, gardener to J. H. Walmsley, Esq., Acton, sent a basket of remarkably fine Chaumontel Pears, which received a special certificate. Mr. Hepper sent fruit of the Telegraph Cucumber, well grown for the season, and in consideration of the cultivation received a special certificate. Mr. W. Holah, Rufford Gardens, Ollerton, sent a seedling Cucumber, which was very much out of condition. Mr. Bull, of Chelsea, sent roots of a Red Beet called Incomparable, some of which were cooked, but neither in colour nor flavour did the Committee consider it an acquisition, or an improvement on other sorts in cultivation.

Messrs. James Carter & Co., of Holborn, sent Globe Tripoli Onion weighing 3 lbs., New Giant Rocca weighing 3 lbs. 9 ozs., two Italian Red, 2 lbs. 6 ozs. and 2 lbs. 11 ozs. These were grown at Naples, and excited great admiration from the Committee, and were awarded a special certificate. Mr. P. J. Perry, of Banbury, sent roots of the Banbury Improved White Spanish Onion, large and handsome, the twelve bulbs weighing 12¾ lbs. They were awarded a special certificate. A special certificate was also awarded to Mr. W. B. Trigg, Hayling Island, for a dish of large and well-grown Shallots. A special certificate was also awarded to Mr. Sidney Ford, for his collection of Potatoes.

Floral Committee.—Rev. J. Dix in the chair. This was the last

meeting of the season, and terminated the labours of the Committee for 1869. The Society may be congratulated on the success of the Tuesday meetings of the passing year, which have been so well attended by its Fellows. These meetings have afforded them an opportunity of seeing and examining a large number of new and valuable plants and flowers: 430 certificates have been awarded to specimens exhibited either as novelties or deserving of rewards for superior cultivation; and when it is remembered that the Fruit and Vegetable Committee have had equal success in the specimens sent to them, we can bid adieu to the labours of 1869 with great satisfaction.

The inclement weather, doubtless, was the cause of the few plants sent to this meeting, and yet there were many of great interest. Mr. Baker, Plumstead, sent a variegated Antirrhinum, which variegation has been often seen before. Messrs. Henderson, Wellington Road, sent a very large collection of Ivies, which were awarded a special certificate. Among them was Hedera rhomboidea obovata, with very dark foliage, which received a first-class certificate. From the same firm came a dwarf Heliotrope, called Jersey Beauty, and Pansy Golden Beauty, very sweet-scented, and useful for bedding purposes.

Messrs. Standish brought fine specimens of their yellow Picotee, very highly coloured and beautifully marked, a Begonia, and cut specimens of six very pretty Bouvardias. Mr J. Atkins, Painswick, Gloucestershire, sent cut flowers of a hardy seedling Cyclamen —hederæfolium græcum, which were highly commended. This plant will be found very useful for rockwork. Messrs. Salter exhibited a variegated form of the common Violet, beautifully variegated, with few flowers; it was requested it should be sent again. Mr. Edmonds, Hayes, received a special certificate for a fine collection of Cyclamens. Mr. Welsh, Hillingdon, also received a special certificate for a smaller collection of Cyclamens, with deep rose-coloured flowers.

Mr. George, gardener to C. H. Marshall, Esq., Caversham, was awarded a special certificate for a well-grown specimen of Calanthe Veitchii, with a spike of beautiful rosy flowers.

Messrs. Veitch received a first-class certificate for Hippeastrum Leopoldii, the flower the King of the Belgians so much admired, and was pleased to allow to be named after himself. This is one of the finest Hippeastrums yet seen, and perfectly distinct from any other. A special certificate was awarded for Messrs. Veitch's group of Orchids, which were very beautiful. Among them was Cypripedium insigne splendens, which was said to be identical with Cypripedium Maulei. From the Society's gardens were two new Orchids, Polycycnis sp., and Lycaste sp., from Costa Rica.

Messrs. Lee, of Hammersmith, sent a very excellent group of shrubs; among them were fine specimens of variegated Hollies, well furnished with berries, and some fine specimens of the Golden Spruce Fir. A special certificate was awarded the collection.

General Meeting.—W. Wilson Saunders, Esq., F.R.S., in the chair. Nine new Fellows having been elected, and the Committee awards announced, the Rev. M. J. Berkeley said he had taken some pains to ascertain the real name of the beautiful species of Abies shown by Messrs. Standish & Co. at the meeting of November 16th. In the absence of the fruit it was utterly impossible to be certain what it was; but on comparing it with specimens at Kew, he found it accorded in all points with Abies obovata of Ledebour. The forms of Picea Pinsapo next came under notice, and it was remarked that the acute-leaved form, known to many as P. cephalonica, appeared to be the sterile state of P. Pinsapo, but that as soon as it assumes the blunt-leaved condition it becomes fruitful. Mr. Berkeley then remarked that the collections of Cratægus and Pyrus at Chiswick were always one of its attractions, and a quantity of the seed having been saved, packets would be distributed to those Fellows who might desire it instead of the collections of flower and vegetable seeds which are annually sent out. A report on the varieties of Maize grown at Chiswick was then referred to, and it was stated that out of a number of varieties sent by the Rev. T. C. Bréhaut, of Guernsey, through Dr. Hogg, the best were a large bright-coloured Maize, and another with large yellow cobs, which both ripened perfectly; and of five sorts sent by Dr. Hogg, the best was Bates' Early Bronze, which also ripened perfectly. Mr. Barron, in his report, remarked that Maize had been grown by Mr. Dancer, of Little Sutton, and it had ripened with him perfectly; also, that Mr. Scarrell, of Littlehampton, had grown it for many years with unvarying success; but it did not seem to him (Mr. Berkeley), that Maize would ever be cultivated in this country as a vegetable. There was another report from Mr. Barron, on Williams' Archimidean lawn-mower, which machine had been well tried at Chiswick, and was very much approved of; but unfortunately, when the Board came to try it, in consequence of coming in contact with a stone, one of the parts, being of cast iron, was broken; but this danger would be obviated by employing wrought iron instead.

The Chairman then said that Mr. Egerton Hubbard, jun., of Leonardslee, Horsham, had offered a prize of £5 for the best essay on the simple practical management of Cottage Gardens, to be printed on cardboard, and to be sold by the hundred to the secretaries of cottage garden societies, with the view of encouraging a better system of garden management among cottagers. He considered it was most important that the Society should encourage the improvement of cottage gardens, and requested Mr. Bateman to ask Mr. Hubbard who was to award the prize, and when.

Mr. Bateman most heartily sympathised with everything that would tend to the improvement of cottage gardens, and considered such efforts would do more to raise the character of the working classes than legislation, though more pretentious. He would suggest two cards, one for the cottagers in the country, the other for window gardeners.

Mr. Bateman then brought under the notice of the meeting an oil painting and a number of other coloured representations of fruits and flowers from Mr. Fernyhough, who had just returned from the Mauritius, and whose first act was alike grateful and graceful in presenting to the Society a fruit of the "Coco de mer" (Lodoicea sechellarum), as well as a portion of the fruiting stem of the Sago Palm. As regards the first-named, the double Cocoa Nut, it was unnecessary for him (Mr. Bateman) to remark upon it at any length, as a few months ago he had made it the subject of a lecturet; and as regards the Sago Palm, it afforded some idea of the power of tropical vegetation. The drawings of plants, one of which was said to resemble a Solandra, and of the Mangoes and other fruits, were then commented on.

The Orchids were next briefly noticed, especially Masdevallia Veitchii, Calanthe Veitchii, and a white variety of the well-known Lælia anceps, which, having only just opened, was rather dingy, but in three or four days it would be as white as the driven snow. A curious plant, too, was the Polycycnis, which, if really new and distinct, he intended to call Reichenbachii.

The Chairman, after moving a vote of thanks to Mr. Fernyhough, announced that the next meeting would be held January 19th, and that the meetings during the ensuing year would be all on Wednesday, instead of Tuesday as heretofore.

WELLINGTONIA GIGANTEA.

I have to thank Mr. Ridgway and others for their information respecting the Wellingtonia; and as so many report an uninterrupted course of success in the growth and appearance of their trees, I am in the hope that the few cases of a contrary kind, one of which has occurred here (Linton Park), may be traced to some local cause. Be this as it may, I am sorry to state that the tree here, that I reported upon some time ago as going wrong, has certainly become worse; and as it had flourished with the vigour common to the Wellingtonia up to the commencement of the hot weather of 1868, I was unwilling to believe that anything beyond suffering from want of moisture was the cause of its bad appearance during the memorable hot weather of the July of that year. A copious watering, however, did not restore it, nor even the ample rainfall of last winter. A steady decline in health, with the dying-off of the lower branches, indicate that something serious is the matter. Now, as the tree was between 24 and 25 feet high at the end of 1867, and is only 26 feet high now, its loss raises the question, Is the Wellingtonia likely to be a long-lived plant or not? The specimen referred to was growing in a favoured situation, there being at a very short distance from it a Thuja Lobbii 28 feet high, and Picea Pinsapo 6 or 8 feet higher, so that I am at a loss to understand the cause of the Wellingtonia going off so unaccountably. We have a great many younger trees of the same species, varying from upwards of 23 feet high down to some of small size, all seemingly most healthy, and one tree, about 20 feet high, has a number of cones upon it. As the Wellingtonias are placed in various situations, the loss of the largest one is by no means explained.

I am glad to be able to endorse what Mr. Ridgway says of the capability of the Wellingtonia to withstand wind, for our finest tree is planted in the open park, and in one of the most windy positions in it, and I believe it is the more robust in consequence. A hexagon fence, with sides of 9 feet, surrounded the tree, and the branches had found their way through four out of the six sides, so that we have been obliged to afford it more room.

I find that, as in the case of the Cedar of Lebanon, there is considerable variation in the appearance of different specimens of this tree, but somehow its detractors are a more numerous body than might be expected. Although I, for one, would be sorry to disparage it as a tree, yet if asked whether it or the Cedar of Lebanon were the more befitting plant for an avenue or a memorial specimen, I would have no hesitation in pronouncing in favour of the latter; but this is a question which can hardly be answered by any of the present generation.—J. Robson.

PORTRAITS OF PLANTS, FLOWERS, and FRUITS.

Eria vestita (Furred Eria). *Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria.—Native of Singapore and Manilla. The plant is clothed with soft hairs. Flowers orange, scarlet, and pale yellow.—(*Bot. Mag.*, *t.* 5807.)

Androsace pubescens (Downy Androsace). *Nat. ord.*, Primulaceæ. *Linn.*, Pentandria Monogynia.—Native of Pyrenees and

Swiss Alps. Densely tufted; flowers numerous and white.—(*Ibid.*, *t.* 5808.)

Blandfordia aurea (Golden-flowered Blandfordia). *Nat. ord.*, Liliaceæ. *Linn.*, Hexandria Monogynia.—Native of wet, peaty soils in New South Wales. Imported by Messrs. Veitch. Flowers yellow.—(*Ibid.*, *t.* 5809.)

Gladiolus cruentus (Blood-red Gladiolus). *Nat. ord.*, Iridaceæ. *Linn.*, Triandria Monogynia.—Native of Natal. Flowers deep crimson—(*Ibid.*, *t.* 5810.)

Vanda Denisoniana (Lord Londesborough's Vanda). *Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria.—Native of Arracan Mountains, on sheltered, shaded trees. Flowers white. (*Ibid.*, *t.* 5811.)

Aloe (Gasteria) Croucheri (Mr. Croucher's Gasteria). *Nat. ord.*, Asphodeleæ. *Linn.*, Hexandria Monogynia.—Native place unknown. Leaves white-spotted. Flowers pink, and green-tipped.—(*Ibid.*, *t.* 5812.)

Clematis.—*Thomas Moore.*—"Of the many beautiful forms of the hardy hybrid Clematis for which the lovers of gardens have to thank Mr. George Jackman and the Woking Nursery, this is certainly one of the finest. It is, in the first place, the largest at present known, since the flowers measure, when expanded, as much as from 8 to 9 inches across. It is, in the next place, one of the most striking and effective in its colours, which effect results from the large spreading tuft of filaments in the centre being white, so that they contrast strongly with the rich violet hue of the sepals, and give the flowers quite the semblance of belonging to some giant Passion-flower. It has the free-growing and free-blooming habit of the other Woking hybrids, and must be set down as one of the best and most distinct of the series."—(*Florist and Pomologist*, 3 s., ii., 265.)

ERECTING A GREENHOUSE CHEAPLY.

I am quite surprised at the very low cost of the "ornamental and useful" house built by a "Yorkshire Amateur;" so much surprised, that I am forced to believe that he obtained glass, wood, bricks, and mortar at a better market than we possess hereabouts. I am very glad that he has succeeded so well and so cheaply, and that he can thus hold out so much encouragement to many who are anxious to have a greenhouse, but count the cost. Like "Yorkshire Amateur," I built myself a house, was my own carpenter, glazier, bricklayer, hodman, blacksmith, putty-maker, &c., and although my structure is of more modest dimensions, my bill of costs amounted to over £3 10s., and was not nearly so well done, I fear, as my success (?) rather varies a "leetle" from the tale just told. Let me trouble your editorial eyes with a few trivialities.

I laid my foundation, thinking "never ventnre never have," and believing that "faint heart ne'er won fair lady," and on a memorable Friday the brickwork and framework were ready for the reception of the sashes. "There's many a slip betwixt the cup and the lip," and while I slept the enemy came in the form of "tornadoes and hurricanes," and what a sight presented itself to my bewildered vision when looking out next morning, fearing, yet hoping!—all was one complete wreck, bestrewed over a bed of Black Prince Strawberries some yards away. Acting on the motto, "Try again," I raised the scattered wreck, found it not so bad as it looked, and by the help of bolts and bars made my work stronger than it ever would have been, had the accident not been. Now, methinks, I'll have the pleasure of seeing my plants grow and do well. Alas! human expectations were the very opposite of every-day realisations. I could not make my plants grow; they made no roots, and what little they had became unhealthy—innumerable hordes of little white worms seemed to eat out the life of them all. I repotted them, and paid them as much attention as if they had been of my body begotten; early and late was I to be found in my "conservatory," still they grew not. Fuchsia cuttings that I received in April are as small as when I received them; Dahlias, that in my neighbour's garden grow to the pitch of excellence required by Mr. Glenny, in mine blossom not like a Rose, but a dog Daisy; my Solanum is happy in the possession of one berry! Dracæna terminalis is as brown as wrapping-paper; Chrysanthemums threw out their buds, showed a flower which cheered my heart and house, and then died from sheer fright at their own audacity. Of the rest, I can safely say no one shames his neighbour, but all vie to be as dull as this very dull weather, and all are as sparing of their flowers as the sun has been of his presence for some time. I feel quite a reverence for a good gardener, for the flowers as surely obey him as the bees do our very able Mr. Pettigrew.

I was glad to see you gave us Mr. Witherspoon's experience, and pleased to see that he elicited several responses, which were very useful to poor beginners like myself. I am pleased that Mr. Witherspoon is so successful. I knew him years ago, and was never aware that he was given to so delightful an occupation as gardening, and as the Cheshire man said to the "Beginner in Bee-keeping," "What one mon can do another can," so I'll keep up my head, and hope still to be a good gardener. At present I am the worst I see, and yet I read your Journal with more relish than Wilkie Collins's "Man and Wife." As Sir Robert Walpole always first opened his gamekeeper's letter, so I first read the Journal out of the batch of papers we are here blessed with on Thursday nights.

Can you give me any hopes of better days, by suggesting a remedy for my many failures?—Ignoramus.

[We feel quite sure that ere long, as respects gardening, you will have to drop your assumed signature, and that some of the best of us may well look after any laurels we have ever obtained. "Trying again, and again, and again," is what makes the man and the true hero. As to the expense of such home-made greenhouses, you would see from our advertising columns how cheaply a neat little house can be obtained with everything ready to be put together, but, as stated the other week, all is not "gold that glitters" in doing all such work for ourselves, if the time and labour are to be counted. This, by the way. In reading the racy account of your failures, we first thought the house may have been built with lime of some particular kind of stone, and that may not have mellowed and sweetened yet; but, then, that could hardly apply to rooted Fuchsias of last April which refuse to grow any larger. Next, we thought that the flue, if flue there is, might be rather fresh; but, then, that could not apply well to Chrysanthemums and Dahlias that should have made their flowering growth chiefly out of doors, and what could so thoroughly kill the Chrysanthemum after yielding its solitary bloom we cannot surmise, unless the root had an extra dose of strong or salt waters. We knew a case where plants could not be made to grow in a certain place, because they gave first a little trouble, and a certain pail came too frequently in contact with the soil in which the roots were placed.

Throwing aside all such ideas, however, and merely premising that besides Chrysanthemums and Chinese Primroses, and forward Camellias and Epacrises, and Winter Heaths, you will not be likely to have much in bloom, unless you can command an average night temperature of from 45° to 50°, we would be inclined to think that your want of success is chiefly owing to two causes.

First, To an ignorance of details rather than of general principles. In such a case as we said last week to "D. J. D.," pages 487 and 488, we would refer you to "Window Gardening for the Many," as most of the details there given will be quite as suitable for your small house as for a window. You will find that much depends on potting, on drainage, on fibrous sweet fresh soil, and the mode of watering, ventilating, &c. With fresh-cured sweet soil you will not be troubled with the little white worms referred to. One of the safest modes of destroying them is to water two or three times with clear lime water, made by putting a shovelful or more of quicklime in a barrel of water and using it when clear. You need not be afraid of the strength, as the water will only hold a certain amount in solution. The best way, however, is to be particular about the soil, and, if at all doubtful, heat it well and then cool it by exposure in a dry airy place.

Secondly, your want of success may be owing to impatience, to an over-anxious desire to see every movement in growth, rooting, &c. Too much kindness may be just as injurious as the want of requisite attention. We have known high-born ladies looking with something like envy on the chubby cheeks and robust frames of the toddling youngsters of their work-people, who were left to run and tumble about as they pleased, the good mother not being wonderfully upset with dust on a frock or a smear on a face. "Must not," carried to an extreme, makes a sad world for a child, and no wonder that under such constant looking-after the cheek becomes pale, and the muscles become weak and soft. So with our favourite plants. Give them what is necessary, and keep them clean, and leave them a good deal to themselves. We can well enter into your feelings if you have been a little impatient. Many scores of cuttings of Pelargoniums, Fuchsias, Myrtles would sooner have become rooted plants if we could have let them alone, but in our beginnings we were everlastingly at them, examining what they were doing below the soil or sand, and with what results

may easily be imagined. The same thing took place when we potted off struck plants in small pots. We were constantly at them, turning out the ball to look at the first white spongiole that found its way to the side, and thus often impeded growth. In all this we may have failed to say a word to meet your case, but it would give us great pleasure to be able to assist you in any way as far as we could.—R. F.]

NOTES AND GLEANINGS.

The schedule of the prizes offered by the Royal Horticultural Society, to be contended for at Oxford in July next, has been issued, and may be had upon application to the Assistant Secretary. The schedule of extra prizes offered on the same occasion by others will shortly be published. In it will be found prizes amounting to £10, offered by the Proprietors of the *Gardeners' Chronicle*, for the best collections of fruit and vegetables; and a prize of £10, offered by the Proprietors of this Journal, for dessert fruits combining excellence of quality with taste of arrangement.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Should frosty weather set in, wheel-out manure to all vacant plots of ground, where heaps may be made and covered with soil till wanted. In many cases, however, it may be trenched-in at once, especially where Carrots, Parsnips, Beet, and Onions are to be grown. All these require to have the soil turned-up some months previous to sowing-time. If dry leaves are plentiful, they may be laid very thickly between rows of choice *Broccoli*, and confined there by sticking-in birch boughs round the outside of the beds. Snow's Winter Broccoli which comes in at this season, if the weather is mild, should be taken up and protected whenever the heads are large enough for use. Great attention must be paid to *Cauliflowers* in frames and under hand-lights; stir the surface round them in mild weather, and give frequent dressings of dry soot, lime, and ashes, taking care also to admit air whenever practicable. Cover *Celery* with dry litter to protect it from frost. Continue to store-up any of the late-tied *Endive* and *Lettuces*, and see that those formerly stored have as free a circulation of air as the weather will permit. All the late *Cabbages* and *Winter Greens* should be earthed-up if not already done. Sow small *Salading* under cover, and protect Turnip *Radishes* in frames. Attend to keeping-up a supply of *Asparagus*, *Sea-kale*, *Rhubarb*, &c., according to the demand and convenience, by introducing quantities of the roots into heat at intervals of about a fortnight. Also see to keeping-up a supply of *Dwarf Kidney Beans*, by making frequent sowings under favourable circumstances. They are generally grown in pots placed in vineries or plant houses, but their liability to the attacks of red spider renders them dangerous inmates of such structures, and where it can possibly be done they should be planted in lines in the bed of a pit devoted to their culture.

FRUIT GARDEN.

Where orchard trees are infested with insects or moss, the bark should be well scraped with a blunt tool to remove as many of the larvæ of the insects as possible, after which the parts should receive a coat of the following composition—viz., hot lime and soot in equal quantities, mixed with water from the cowhouse until it attains the consistency of thick paint. This composition should be well rubbed into the crevices of the bark in order to make sure of its reaching every hiding place of the enemy, and if a little cow manure were worked-up in the composition, it would be useful in causing it to adhere better. It is a tedious task to properly cover old large trees with this, but its effect in clearing them of insects will repay the trouble, and an occasional coating to young trees will be useful in keeping them clean. Gishurst compound applied as a strong lather is also recommended for the same purpose. Strawberries may now be placed in a pit or frame where the temperature can be kept at about 45°, giving plenty of air whenever the weather will permit, and if the pots can be plunged in a gentle bottom heat, this will be advantageous in encouraging a healthy root action.

FLOWER GARDEN.

Wheeling can be more expeditiously and cheaply carried on in frosty weather than when the surface of the ground is soft; hence, where wanted, fresh soil or manures should be put upon the flower beds and borders. Shrubberies may also be thinned, where this involves only the cutting-out of overgrown plants or lopping deciduous trees, but where evergreens generally require pruning it is best done in March, for although when the winter proves mild such work may safely be performed at any time, it is never safe to depend upon this.

GREENHOUSE AND CONSERVATORY.

In frosty weather be satisfied with as low a night temperature in all plant houses as will be safe, taking advantage of bright days to increase the temperature, and using a little fire heat to dispel damp. The proper night temperature for conservatories very much depends upon the kind of plants they may contain. Where Camellias, Epacrises, Heaths, and other winter-blooming plants form the principal inmates, 40° will be sufficiently high, and with a dry atmosphere it may safely be allowed to sink a few degrees on hard nights, but in cases where the hardier kinds of winter-flowering stove plants are brought in while in bloom, 45° should be considered the proper mean night temperature. Let whatever watering may be required be done early in the day, so that advantage may be taken of sunshine whenever it may occur, to give air for the purpose of drying the foliage, &c. Many persons appear to entertain an opinion that very little attention is needed to properly supply plants with water at this season, and they look over their stock at intervals of several days. We would, however, caution young gardeners against this mistake, and advise them to examine every plant at least every alternate day, deferring the application of water until it is really required, and then giving a liberal soaking. Attend daily to the removal of dead or decaying leaves, and directly any of the flowering specimens become shabby remove them to some out-of-the-way place, taking care that they are placed under proper conditions as to temperature, &c., according to their wants, and supply their places with others in full beauty. Where necessary, the leaves of plants should be sponged over and thoroughly cleaned, and climbers pruned, trimmed, and put in proper order for the spring. Soils, crocks, and charcoal, and whatever else may be necessary for potting, should be in readiness for use when wanted. Let heat be applied to all plant structures moderately for a time; do not, because the weather may be severe, apply constant parching heat, let the heat be moderate with humidity, very moderate at night, and on light days when air can be admitted without injury a little additional heat may be employed. Always regulate the night temperature by the degree of external cold. Do not attempt to maintain the same degree of internal heat to any structure when the temperature is below the freezing point, as you would were it 10° or 15° above freezing. It is in many cases difficult to maintain a sufficiently moist atmosphere without causing drip, as the moisture in the house becomes condensed upon the glass, and unless provision be made by means of inside gutters and pipes to catch the condensed moisture and carry it off, it is nearly impossible during frosty weather to preserve the beauty of the flowers for any length of time; and in cases where there is no provision made against this kind of moisture falling upon the plants, the temperature should be kept as low as may be consistent with safety, avoiding moisture in the atmosphere as far as possible whenever the glass is affected by frost.

COLD PITS.

Where the stock of bedding plants has to be wintered in structures of this description, the present will be found a trying time, and the utmost vigilance and care will be required to preserve the plants from harm. Apply sufficient covering to the glass and to the walls of the pits or frames to ward off the effects of the most severe frost, and embrace every chance of admitting fresh air and removing decaying leaves in order to prevent damp and mould. Too little water can hardly be given at present to plants in cold frames; and when it becomes necessary to give any, let it be done in the morning of a fine day, freely admitting air afterwards in order to dry up all superfluous moisture before evening. Plants when covered up for several days should not be suddenly exposed to bright sunshine, but should be partially shaded for a few hours, admitting air in the meantime if the state of the external atmosphere will admit of it. This will dispel damp and greatly assist in preventing the injury which might otherwise result from sudden exposure to sunshine. Look frequently over everything subject to the attacks of mildew, apply sulphur the moment this pest makes its appearance, and see that everything is perfectly free from insects. Anything of which there is but a short supply of plants to propagate from, should be placed in growing quarters at once, taking care to keep the plants near

the glass and free from insects, &c., for softwooded plants in heat at this season are very subject to the attacks of insects.—W. Keane.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

As during the finest days we were engaged on some extra ground work, very little has been done out of doors, as the heavy rains were unsuitable for digging and trenching; and, in truth, from the crops in the ground, until we get Celery, &c., off, we have but little unoccupied space to go to. As stated last week, however, such work may be proceeded with where work of other kinds is at all scarce. For wet days we have plenty of work in washing, cleaning, glazing, stake and stick-making, tally-cutting, &c. We do not complain much of slugs, grubs, snails, &c., mild though the weather now is, but alike to exposed and protected plants mice have been very troublesome. They seem to eat out the centres of young Cauliflowers, Pinks and Carnations, Strawberry plants in pots, &c., as much for the pleasure of being mischievous as anything else, as on examining the débris, almost the whole is left behind.

Stirred the ground amongst young Cauliflowers, Lettuces, and Cabbages when dry enough to do so, and placed cones of burnt earth and ashes over Artichokes, Sea-kale, &c. This protects the exposed heads of Sea-kale, not so much from frost, for it is hardy enough, as from birds and mice, as without protection we have had the large plump buds picked out by blackbirds and thrushes, and rats and mice. None of them care about putting their bills or noses freely in such material, and for this purpose the burnt earth and rubbish seem to be more effective as deterrents in proportion to the alkaline matter from burnt weeds, burnt remains of vegetables, &c., contained in the heap. In proportion to the amount of saline matter, also, do slugs, &c., keep aloof from it. The very fact of the combustion makes all such earth unpleasant to them.

FRUIT GARDEN.

This week we must merely refer to previous numbers and the excellent remarks of Mr. Keane. We moved a lot of plants to one side of one of our orchard houses, and were thus enabled to give the trees and walls a good syringing with water nearly at the boiling point, using a thick cloth for the hand resting on the middle of the syringe. Of course such water becomes considerably cooled before reaching the twigs of the tree, but still it is hot enough to kill the eggs of most insects, and any live insects themselves. This syringing will be repeated several times. We never knew an instance in which this *hot-water syringing* did any harm to deciduous trees when in a dormant state. Washing, scrubbing, and even painting with compositions with brushes, often injure the buds, even by unsettling them or unfixing them a little, making them liable to drop afterwards, and some of the mixtures for painting twigs, &c., require themselves to be used with care, as when very strong they are dangerous. In many gardens it is difficult to obtain hot water, as we have ourselves experienced. We have been obliged to borrow often from hot-water pipes—a mode of proceeding which is attended by several drawbacks. Hot water is so valuable for watering and cleaning, that were we to have a general garden as a commercial undertaking, we would make sure of having a little boiler to yield pure hot water at will. We could then easily add soap or whatever was necessary to it. With plenty of this at command we should have less trouble from insect enemies, and less occasion to use smokings, powders, and mixtures. Hot water on all deciduous plants in a state of rest is the safest and best insect-preventive. Warm water may well be used at times even on a growing plant; but in such cases a caution must be taken that the water is not too hot. We have often used it as high as 120° or 130°, and a little more, and with none but beneficial results. We would not think of doing so to a plant completely free from insects, but for soft-skinned insects a forcible syringing with such warm water was as effectual as washing with some nasty mixture, or smoking with tobacco in any of its forms.

ORNAMENTAL DEPARTMENT.

Besides potting, encouraging bulbs, helping on Roses, as alluded to lately, we have begun giving a general clear-up, sweeping and rolling the pleasure grounds. Tree leaves, like other refuse, are most valuable in their own place, but they cause melancholy feelings as they drift dead and decaying on the green lawns. There will be enough of the saddening, and, we trust, of the truly heartfelt practical sympathising with sorrow and trouble in these days, without decaying leaves obtruding too near the cheerfulness of Christmas times. The weather on the whole has been so mild, that the grass in many places had grown so much as to need a slight sweep with the scythe before being followed by the broom and the roller. The sweeping was done much more easily and better in consequence. Lawns should never be mown now or in spring if there is the slightest crust of frost on them. It injures them greatly, often kills the best grass outright, and at other times takes them months to put on their full green livery. A chop-over thus late with the scythe or machine, if done in mild days or mornings, often answers better than doing it early in spring, as the lawns do not suffer from the parching east winds of March, but a continuous rich green is maintained all the winter and spring, until it becomes necessary to give the first general cutting or mowing.

Let me conclude by observing the pleasure which it would give me to see, if not shake hands with our older readers, with whom I have been privileged to hold an unbroken weekly communication for so many years, and at least be permitted to express my earnest hope, that all connected with "our Journal," in whatever way, may experience in this hallowed period of the year, that the source of their happiness is more lasting than even our evergreens.—R. F.

COVENT GARDEN MARKET.—December 22.

We are not able to obtain any advance in prices on former quotations, the market being heavily supplied. The chief demand is for rough goods and Christmas evergreens.

TRADE CATALOGUES RECEIVED.

Weeks & Co.'s "Gardeners' Pocket-Book" is given to gardeners. Although the object chiefly aimed at by the firm is to draw attention to their hot-water apparatus, yet the pocket-book deserves much commendation, for it contains tables useful to gardeners, an almanack, and a diary.

Sutton & Sons, Reading.—*Suttons' Amateur's Guide and Spring Catalogue for* 1870.

TO CORRESPONDENTS.

N.B.—Many questions must remain unanswered until next week.

Books *Cordon*).—"Cordon Training" by T. C. Bréhaut, is published by Messrs. Longman. (*W. S.*).—The Rev. S. Reynolds Hole's volume is called "A Book about Roses." The price is 7s. 6d., any bookseller will obtain it for you. (*G. Coombs*).—We do not know where you can obtain numbers of Paxton's "Magazine of Botany." It ceased to be published twenty years since. You will find "The Florist and Pomologist" an elegant and cheap pictorial monthly, with beautiful coloured plates of all the new plants.

Florist's Business (*Y. Z.*).—Judging from your letter, we conclude that you have no acquaintance with such a business, and, if so, you had better let the seven houses and land. We cannot advise you, not know-

ing anything of your neighbourhood, objects, or acquirements. If you enter into the business, your best guide will be to do as the most successful florists and market gardeners in your vicinity do.

Late Pears (*Wyeside*).—Beurré de Rance will do well on a wall, and comes in after Josephine de Malines. Doyenné d'Alençon, or, as it is usually called, Easter Beurré, and Bergamotte Esperen, will do well on a wall.

Dark Hybrid Perpetual Roses (*Inquirer*).—Black Prince (W. Paul) and Horace Vernet, or Pierre Notting.

Cucumbers Bitter (*Cucumis sativus*).—The cause of Cucumbers being bitter is their not being grown quickly. When grown in a temperature of 65° at night, and 70° or 75° by day, they rarely are bitter. Very often they are bitter from being allowed to grow to a great size, whereas they should be quickly grown and cut whilst young.

Blackberries (*Berkhampstead Subscriber*).—The common Blackberries are not worth introducing to gardens, but, if they are desired, now is a good time to transplant them, selecting the smallest plants. The ground should be trenched, working in a liberal quantity of manure. Rather light, well-drained soil is best. Plant them in lines 6 feet apart, and 3 feet from plant to plant. The canes may be trained to stakes in a similar way to Raspberries. The Lawton and Dorchester Blackberries are far better than the common sorts, bearing much larger and better-flavoured fruit. There is a new variety from France, the Rochelle, said to be even superior to the Dorchester and Lawton. The latter we have grown very fine, and we find them useful for tarts, &c., in autumn, for they bear until frost stops them. For covering low walls, palings, or anything unsightly, they are both useful and ornamental, requiring but little attention.

Protecting a Vine Border (*Another Amateur*).—By covering the border with the frame you will be able to ward off wet, which it is desirable to do in winter, as well as to secure a considerable amount of warmth, by keeping the frame closed at night, and in dull, cold weather. It would be a good plan to keep it on until May. From this time till then it may remain closed, except that after March the lights may be drawn off on fine days, and to admit gentle rains, using them for protection from frost, and to keep off heavy continuous rains. In severe weather a covering of mats or other material, in addition to the lights, ought to be given, so as to prevent the border from freezing, or you may mulch it with 3 inches of short littery manure. This would act both as a protection to the roots against frost and as a manure, the lights keeping the border from becoming saturated with rain.

Time of Grapes Ripening (*Wm. Hilloak*).—The Vines you mention, Alicante and Child of Hale, will ripen their Grapes at the same time, and under the same conditions as Lady Downe's.

Melons and Celery (*J. W. C.*).—For frame culture no Melon surpasses Beechwood, and for exhibiting, Meredith's Hybrid Cashmere, though we find few Melons equal Beechwood if true. Of Celery, Manchester Red is good for a general crop, and for its keeping qualities incomparable White. It is, undoubtedly, the best white Celery in cultivation, either for early or late use.

Vines from Eyes (*Idem*).—The Vines from eyes in 4-inch pots should now be cut back to two eyes, have the soil shaken from the roots, and be potted in the same size of pot. When the Vines begin to grow, transfer them into larger pots as those they are in fill with roots, and by June, if encouraged with a gentle heat and moist atmosphere, they may have their final shift into 9 or 11-inch pots. By autumn they will be strong canes, fit for planting out next spring but one, or they may be fruited in pots, taking care to have the wood thoroughly ripened.

Vine Propagation from Eyes and Cuttings (*Con amore*).—The canes intended for propagation should, at the time of pruning, be reserved, and be kept with the ends in moist soil until the end of January, when the eyes should be prepared for insertion. From the back of each eye make a cut with a sharp knife slopingly upwards, bring it out about three-quarters of an inch above the eye, and on the same side as that on which the eye is situated; a similar cut is made downwards, and then the eye is ready for insertion in a 4½-inch pot, laying it horizontally, eye upwards, and covering with about half an inch of fine soil. The soil should be moist, but not very wet, and should always be kept moist without being made so wet as to become sodden; the pot to be plunged in a bottom heat of 80° to 90°, and not less than 70°, with a top heat of 60° to 75°. In this the eye is to be kept until it has made a shoot nearly a foot long, when it may be transferred to a pot 7 inches in diameter, replacing it in the hotbed, which at this period should be at 70°. By June the Vine will demand a pot 11 inches in diameter, and with liberal treatment in the way of moisture and heat, will make a strong cane by September, probably capable of bearing a good crop next year in a pot, and it will do for planting. Without bottom heat the eyes should not be put in until March, and even then a slight bottom heat is necessary, removing them to a greenhouse when the heat in the hotbed declines, or when they interfere with the growth of the other occupants by becoming too large. Cuttings may be of the last year's wood, with two, three, or more eyes, inserting them so deeply in the soil that the uppermost eye is only just level with the surface. The best cuttings, however, are those with 2 or 3 inches of the two-year-old wood, and one eye of last year's wood. Cuttings of greater length may be made, and be planted at once in the border, but the shorter they are the better, in our opinion, for the ultimate progress of the Vine.

Poinsettia pulcherrima Leaves Falling (*X. X. X.*).—It is a result of imperfectly-developed growth. The plants should be grown in small pots, and be kept in a light, airy position, and near the glass during the summer. They are roasted and stewed in summer; when autumn comes they are dried and starved, and the leaves fall, nothing being more ungainly than this plant badly grown, though, when well grown, very fine for decorative purposes. It requires a cool stove, and may succeed in a warm greenhouse if the plant be kept dry in winter. The soil should be kept moist, but not excessively so, even when growing. In winter give little water, only enough to keep the wood from shrivelling. The Mandevilla suaveolens we should plant out in a border. It would be less troublesome as regards watering, and would make freer growth and better foliage.

Dressing Orchard-house Trees (*An Amateur*).—Though the trees are apparently free from insects, it is desirable to dress them when at rest, for the Peach aphis is apt to be very active even in winter, and the winter dressing is an excellent destroyer of scale. We consider 8 ozs. of soft soap, 8 ozs. of tobacco powder, and 2 lbs. of sulphur to two gallons of water, make an excellent wash. It should be boiled in a pot over a gentle fire for ten minutes, stirring it all the time, and when cooled to 120° it may be applied to every part of the trees with a clean paint brush, rubbing it into every crevice, and taking care not to dislodge the buds. This should be done in mild weather, and the sooner the better. In dressing Peach and Nectarine trees, care must be taken to draw the brush upwards, not downwards, otherwise the bloom buds are liable to be displaced.

Fig Propagation (*Yorks*).—The best time to propagate Figs is in January, or the beginning of February, if you have a good heat of from 70° to 75°, and a bottom heat of 80° to 90°; if not, defer it until the beginning of March, or until you have a bottom heat of not less than 75°. They are best raised from eyes of last year's wood, which may be inserted either perpendicularly or horizontally in the pot, and should be covered about half an inch with light soil. Keep them moist, but not very wet, and in a brisk bottom heat the eyes will soon make good shoots and roots. They should be inserted singly in 3-inch pots, and when rooted may be shifted into larger pots, and forwarded in gentle heat. Cuttings will also root freely, taking off shoots close to the stem, inserting them two-thirds of their length in the soil, and plunging them in a bottom heat of not less than 70°. Plants from eyes are ultimately the best, but those from cuttings become larger in less time. For cuttings, we like the short stubby shoots produced near the base of the tree, and of one year's growth only. We have fruited these in the year they were put in.

Praise (*A Second Gardener*).—All that you say is true, but would be out of place in our columns.

Briar Cuttings (*Julia*).—It is very likely that cuttings of the Dog Rose or Briar would strike root freely if now put in, though November is a better time. The cuttings should be of the well-ripened wood of the current year, cutting the shoots into lengths of about 10 inches, removing the eyes for two-thirds the length of the cuttings, so as to prevent the eyes below the soil from throwing up suckers. Insert them two-thirds their length in the soil.

Destroying Mice (*Eve*).—The best means of preventing mice devouring Crocuses in the open ground is to set a few traps baited with a small Crocus bulb. The common brick or figure-of-4 trap will be found the most serviceable. Set the traps near to where the Crocuses are attacked, closing up the holes, and remove every part of the roots brought up and partially devoured by the mice.

Gesnera zebrina Compost (*A Lady in Cheshire*).—Two parts fibrous loam, one part leaf soil or old cow dung, and one part sandy peat, with a free admixture of sharp sand. The pots should be well drained. We have known the roots destroyed by too-powerful doses of liquid manure.

Melons and Cucumbers in the Same Frame (*E. E.*).—You cannot well grow both in a two-light frame, for when Melons are setting and the fruit ripening they require a drier atmosphere than is suitable for Cucumbers, which at all times need a moist atmosphere to secure a succession of crisp good-flavoured fruit. By having a boarded partition you might have Melons under one light, and Cucumbers under the other, and then you could grow both, for they require but little variation in the soil and bottom heat. It would be much better, however, to grow them in separate frames. Beechwood (true), is one of the best, if not the very best of green-fleshed Melons in cultivation. It is the best hardy frame Melon.

Melon for Preserving (*E. E.*).—Bignell's Scarlet Flesh is an excellent kind for preserving. Conquerer of Europe is another good sort, and pale green in flesh.

Planting Strawberries and Fruit Trees (*A Poor Lady*).—You may next March procure runners of this year that have been put out in nursery-beds, and, by moving them with good balls, and carefully planting and attending to them with water, you may have a moderate crop next June or July. For cropping Rivers' Eliza is better than Sir Joseph Paxton, but it is not so early as the latter. The former, for its heavy cropping qualities, ought to be in every garden. You may probably obtain plants in small pots, and those put out early in March would give you fruit next year, or the summer of planting. February, during mild weather, will be a good time to plant the fruit trees, but they may be planted now, though we consider midwinter about the worst time in the year, especially in cold wet soils, and during wet weather when the ground is very often nearly mud. Court of Wick and Sturmer Pippin are two good winter dessert Apples. Two Plums for standards are Diamond and Perdrigon Violet Hâtif. Planting Rhubarb from now until March will afford a supply of stalks next spring, but to do well it ought to be little cut from the first season.

Compost for Chrysanthemums (*A Constant Reader*).—Two parts loam from rotted turves, and one part leaf soil or old cow dung not less than a year old, with a free admixture of sharp sand, will grow them well. Hard potting after the plants or cuttings are struck should be practised, as it prevents lanky growths, and keeps the plants stiff, shrubby, and short-jointed. The Primulas we should think are very fine. Being good in foliage, with large, well-bloomed trusses nicely elevated above the foliage, the plants examples of good cultivation, they certainly would be fit for exhibition, but though size of bloom is a merit, other considerations are of equal moment.

Desfontainea, &c. (*E. M.*).—Any of the principal nurserymen who advertise in our Journal could supply you.

Cider Apples (*Coventry*).—The delay has arisen from our applying for trustworthy information. You will see a reply in our Journal to-day. The Normanton Wonder is only another name for Dumelow's Seedling. Being very juicy and rather aromatic, it would produce probably a good cider.

Atmospheric Moisture in Vineries (*Amateur*).—In a long answer to a correspondent, you will see that atmospheric moisture for Vines is pretty fully considered. One thing is there omitted—the impropriety of syringing or watering pipes or flues to obtain a moist vapour. That plan is very fitful in its operation, and besides that, there are other objections, such as obtaining vapour at times too hot to be suitable to plants near it. The best plan for securing atmospheric moisture is to have evaporating vessels made of zinc, tin, or cast iron, to fit on the pipes or flues; then the vapour will be in proportion to the heat. Some time ago we alluded to the importance of the fixing accurately. Some vessels, 2 feet in length, with a semicircular form beneath to clasp the pipe, we

found bedded in a thin layer of white lead at the two ends merely, and they took double the time to evaporate the water placed in them which similar vessels did that had received a bedding all their length: hence such evaporating troughs cast on the pipe are better than any merely placed on it, though bedded. These evaporating vessels should always be placed on the flow pipes. Your proposed mode of wrapping sphagnum moss tightly over the lower or return pipe, and sprinkling such moss twice a-day with water, would only be just better than sprinkling the pipes at once now and then. We know that many hold a similar opinion to that which you entertain—namely, that thus the pipes would send off more heat by evaporation continually going on. With all respect, we do not agree with you, for first, as shown some time ago, the more evaporation proceeding from a surface the more will that surface be cooled. Then, secondly, unless you water the moss-covered pipes more than twice a-day, the rising of vapour will not be continuous, for as soon as the moss next the pipes becomes dry, the dry moss will act as a non-conductor of heat, and if the moss is at all thick, the outside layer, though damp, will emit little more vapour than if the moss were laid on the ground near the pipes; and lastly, when the moss gets dry round the pipes, the pipes themselves may become hot, but the heat will not be radiated freely into the house.

NAME OF FRUIT (*J. Bryan*).—Your Apple is Coe's Golden Drop.

NAME OF PLANT (*J. E.*).—That which you enclosed is not the seed, but part of the seed-vessel, of the Honesty, Lunaria biennis.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending December 21st.

POULTRY, BEE, AND PIGEON CHRONICLE.

COMMITTEEMEN EXHIBITING.

THE question of committeemen being allowed to exhibit, which has been so much discussed lately, is a most important one; and in adding a few words in support of the views of "ALIQUIS" and others I would suggest that the matter should be regarded, not with reference to the interests or wishes of exhibitors, committeemen, or any mere individuals whatever, but to the general and most lasting interests of the poultry fancy itself. Individuals may be dissatisfied, or may even be really aggrieved; but there are many things to be considered ere it is concluded as best on the whole for officers to be prohibited from competition; and this large view of the question, it appears to me, "EGOMET" and others have somewhat lost sight of.

One of these things was touched upon by "AN OLD COMMITTEEMAN," when he mentioned the effect of such a rule at Bristol or Birmingham, in a way the force of which was evidently felt by "EGOMET." Let me recall his argument, but in more definite terms. Suppose at Birmingham Mr. Mapplebeck's and Mr. Tomlinson's Buff Cochins had been debarred from competition; suppose at Bristol the Spanish of Messrs. Lane, Parsley, Roué, and Jones must have stood aside; suppose at Beverley, Middleton, Whitehaven, and the Yorkshire shows, various well-known yards of Game, Bantams, and Hamburghs could not compete, I think it cannot be denied that at these shows an inferior standard of beauty would be held up for imitation, and beginners and others would not have before them a true idea of what perfect birds should be. To put this into general terms, that in every place the best birds should be shown and should win, seems to me, if poultry-keeping be not a mere useless hobby, to be of all points the most important of all; and if it be lost sight of, the effect in the end must be that localities now celebrated for certain breeds will lose their pre-eminence from want of a true ideal, for the same exhibitor seldom continues beyond a certain period; and if the *new men*, which are the life of the fancy, cannot see the best models it needs no prophet to foretell the result.

"EGOMET," however, replies to this that the breeders in question should withdraw from the committees, and that there are "plenty of others capable of taking their places." From personal knowledge of the two principal shows named I can say that this is a mistake; that it is the actual breeders of poultry who, as a rule, are the life and soul of a committee; and that with regard to the Bristol Show, it would never have been attempted but for the first determined efforts of a few exhibitors alone. I repeatedly notice that in most cases the withdrawal of a name from the ranks of exhibitors is followed by retirement from committees also—there is a case at Bristol this very year; and careful and extended observation of many schedules has convinced me that only fanciers and exhibitors are likely, or even able, permanently to do the real work of a show.

Finally, I may state that since this discussion commenced I have taken the trouble of asking many members of several important committees, who all assure me that in point of fact they themselves would not only resign their office, but their committees would totally break down, were such a rule attempted to be enforced.

I think, further, that with the best of our judges no dissatisfaction would ever arise. Fancy any committeeman "trying it on" with Messrs. Hewitt or Teebay. I think I see him do it! Everyone knows the readiness of those gentlemen to oblige where they can, but everyone knows too, or may know if he only try, that such an attempt would only succeed in "blackballing" even the finest pen in the world. To suppose any of the recognised judges, as they may be called, capable of such criminal weakness is not only an insult, but is tantamount to confessing we may as well refuse to show altogether, for others besides committeemen can "work the oracle" at a poultry show. Have good judges, and we shall—bar occasional mistakes which must occur—have good awards.

Yet there have been glaring cases. It is of no use to deny this; and the question is, What is the remedy? I reply without hesitation, Systematic, fearless exposure. No need of strong language; simply state the facts—*e.g.*, "At —— Show last week a member of the Committee named —— took —— prizes evidently not deserving them. He was seen to converse with th Judge, who was Mr. ——." This carried out regularly woul soon answer all needful ends. It is well to remark, however that a committeeman may deservedly win many prizes, and an angry competitor will do well to obtain disinterested opinion ere he makes complaint. But if he be clearly in the right no judge —for it must be really him with whom any actual guilt lies—could stand repeated exposure of such falsity to his trust.

One word finally. I was much struck with "EGOMET'S" refusal to consider "ALIQUIS" as an "opponent." It did me good. I shake hands with him mentally, and may his health be eaten in every fowl killed between now and Christmas! I really do think the fancy is "looking up" when good men and true—kindly, hearty, Christian gentlemen, meet round the centre line of "our Journal" pages, and in good fellowship and good will discuss earnestly all that bears upon the pursuit they love so well. The best interests of the fancy are what we all have at heart, and in the end will come out benefited by all that thus takes place. It was so, for instance, in the trimming business. In prominently ventilating this subject last season I manifestly injured my own individual interests in every way; yet I got many hard knocks, and views and opinions were freely fathered upon me which I never penned. I am not prepared to say no word escaped me which I would wish recalled; but in a great measure the object was gained, and I have the pleasure of knowing now that some of the judges, at first naturally irritated by what they thought intended for censure upon them, have long since given me credit for very different feelings, and learnt to rejoice that the question was brought forward. It will be the same in this discussion. What is mistake on either side will pass away to be forgotten, but all that is good will remain for the prosperity of the fancy and for the benefit of us all.—L. WRIGHT.

MORE TIME FOR JUDGING.

IT is high time that the committees of management of poultry exhibitions should make arrangements for the judges to have

more time for examining and awarding prizes, and that the judges should not be inconvenienced by the admission of the public during the time they are going round. It is doing great harm to our shows, for exhibitors are losing confidence in the decisions made so hastily, in consequence of which many valuable specimens are not shown. Complaints are daily to be heard respecting birds having been overlooked, and inferior specimens having obtained prizes or commendations.

I do not think the judges are to blame, for how can any person, however experienced or qualified for the business, make a true and impartial selection in so brief a space of time?

In two shows lately, for example, supposing each pen of birds to have received its allotment of the time taken by the judges in their round, forty-five seconds were occupied; and at another recent show each pen on the average must have obtained twenty seconds. Cannot some arrangement be made, so that the judges may give more time and be quite undisturbed in making their awards?—Aliquis, *Chesterfield.*

ANNALS OF MY POULTRY YARD.

Reinette is dead! and I have to mourn, not only the loss of a beautiful Sebright hen, but over the barbarity of her companions. The three spent last year in peace and harmony in one pen, and were cherished and admired to their hearts' content, which is saying much considering how much admiration is required to content the heart of a Bantam cock. Well, time went on, and matronly cares occupied Reinette and Jeanette; and though they were not fortunate in bringing up a large proportion of the lovely chicks which were hatched by them, each was exemplary in the fulfilment of all her duties of hen-life. Again the seasons rolled on, and the Comte de Morny, Reinette, and Jeanette were put into their old quarters; but in lieu of peace and harmony came strife and persecution. Reinette was pecked and driven from her food, first by Jeanette and then by the Comte, whose vanity I verily believe made him a ready follower of Jeanette in her wicked practices. I was careful to give the poor little queen a good meal whenever I had time to go to her, but that was not always; and her share of sorrow was so much greater than her mede of kindness that she broke down, as others of her sex have done under like trials.

We returned from the world's great poultry show (I and the bird-fancying part of my family), and were shocked to hear, of course before any pleasant news could reach us, "Reinette is dead!" Then my "man Friday" said, "There, ma'am, I found her, standing like a poor penitent in the corner of the house, dead." We were all sorrowful, and to some of us tears came, because only on our journey homewards had we said, "To-morrow Reinette shall be put into another house, for the Comte de Morny and Jeanette will never be kind to her again." Alas, too late! And I marvel that a tiny bird, once gentle and loving to his little hen, should have been weaned from his allegiance and turned from his cherishing by the machinations of another, precisely as one has seen in bipeds of higher standing, though not of higher *under*standing, it may be.

Cruelty I have ever held in abhorrence whether in man or beast, and as long as I can remember I have waged war against it. Hence I confess to feeling almost revengeful now, and to wishing that I may "find a Tartar" to replace the poor little murdered bird, for I am at a loss to devise other punishment for the Comte de Morny and his wicked mate.—W.

PRIZES FOR FRENCH VARIETIES OF FOWLS.

In a recent number of "our Journal" I read that committees of poultry shows were willing in general to establish separate classes for the French varieties, conditionally that fanciers of those varieties would either guarantee a certain number of entries in such classes, or offer silver cups as first prizes. The guarantee plan would not, I think, "take with the public," as it might be difficult to ensure a sufficiency of entries unless the prizes offered were liberal, which has not usually been the case at those poultry shows where classes for the French varieties are already established, and there would certainly be a difficulty in finding guarantors. The cup scheme seems more likely to succeed if exhibitors and breeders will but amalgamate, and endeavour mutually to promote the common interests. I know that there are at least fifty exhibitors of Houdans in Great Britain whose names have appeared in the prize lists of "our Journal," and supposing forty of them willing to subscribe 10s. a-piece, four five-pound prizes might be offered, one at each of four poultry shows that might be selected, so as to suit the convenience of all persons concerned. For instance, if Halifax, Liverpool, Ipswich, and Southampton were, with the sanction of the respective committees, the shows agreed upon, Scotch, north-countrymen, Irish, Welsh, midlanders, southerners, together with the Isle of Wight and Channel Island fanciers, would all have an opportunity of competing for some one of the four prizes without having to send their birds an unreasonable distance from home.—H. Seymour Fraser, *Headley, Hants.*

MALAYS.

"Malays ought to show better in numbers and general merit," such is your verdict on this breed at Birmingham. Is not this rather harsh judgment? There were seven entries of old hens—five of these were noticed by the Judges. I do not write quite positively, but I do not think any other class of fowls at that Exhibition received an equal amount of commendation; This is at least a feather in the cap of the despised Malay. "These entries were more numerous years ago than they are now." Of course they were years ago; at almost every show there was a Malay class. Where are those classes now? I have often in your pages urged on the committees of our larger shows the duty of making classes for every known breed of any standing. I have urged this, because the variety of fowls is one of the charms and attractions to visitors, and because the plea of the entries not paying the prizes is not just, because in many of the other classes the entries largely overpay. Poultry shows profess to be for the encouragement of the improvement of domestic poultry. Truth compels me to add that the encouragement offered to Malays has been mighty small—perfectly microscopic. I think I am correct in writing that Birmingham is the only place that now offers the Malay a class—shall I call it an asylum? Bristol and Clifton, with its splendid prize list, ignores them—does it, or rather did it contemptuously, for at the show three years ago, when they opened them a class, there were eight entries. Was this a reason for withdrawing the prizes altogether the following year? And what was the result? One miserable pen was entered in the "Variety" class. Take again the new, and I trust permanent London show, where is the Malay class there?

In the face of these difficulties, and with the decreasing popularity of the breed itself, is it wonderful if they deteriorate? Is it not more wonderful still that any admirers of the Malay remain? I own there are difficulties in the way of keeping them. I admit they are not the most beautiful of our feathered friends, but certainly while the French breeds exist they are not the ugliest. They are not the most profitable, but on this score they deserve more credit than they obtain. They are in my humble opinion second to none for flavour on the table; and as to early laying, I have three out of six pullets this year now laying, and we are still a fortnight before Christmas.

A word on another subject—competing committeemen. I wish to simply say that I regret "Egomet's" strictures, and think that "An Old Committeeman" has much the best of the argument. Having never acted in that capacity, and being quite unwilling to try my hand, I say, Let them by all means compete, and then let the best pen win.—Y. B. A. Z.

MANCHESTER POULTRY SHOW.

Although, most probably on account of the numerous exhibitions now taking place, the number of pens was a little short of that of last year, the superior quality of the generality of the classes has certainly never been exceeded at any of the previous Manchester exhibitions. The same punctuality and perfection that have marked all the arrangements of the former meetings were as fully carried out on the present occasion, and the weather, though not so fine as could be desired, was upon the whole as favourable as could reasonably be expected at this season. It would be useless to enumerate the advantages of the Belle Vue Music Hall for the purposes of a poultry show, as few of our prominent exhibitors have failed to see them for themselves. We cannot, however, forbear to call attention to the excellence of the ventilation, the diffusion of light throughout, the liberal amount of space allotted to each pen, and last, though not least, the constant supervision and care personally bestowed by Messrs. Jennison on the very valuable specimens entrusted to them.

The *Dorkings* were remarkably good, the classes for hens and pullets especially so. Some remarkably good rosy-combed Grey Dorkings were on view, and the entry of White Dorkings was far beyond common. In the *Spanish* classes no previous Manchester show has equalled the late one, and although many of the adult cocks of this variety were scarcely in full condition, many of the best birds in the kingdom were easily recognisable. Most of the Spanish hens and

pullets, however, were in perfect plumage. The best show of *Cochins* which we have seen this season took place at Manchester, and certainly the Partridge-feathered were such as will only be seen together again at very long intervals. In the classes for Buffs and Cinnamons the exhibition was particularly strong; and in a class where most of the Buff birds shown were excellent, a Cinnamon cock of great size, and of very unusual colour and conformation, took the third prize. This valuable breed is now almost extinct, and it has not been prominently exhibited anywhere for some years past. Some of the most remarkable Buff Cochin hens and pullets that we have seen for many years were exhibited. The White Cochins were few in number, but they were such as might be looked for in vain at a long succession of our largest shows. The *Brahmas* formed some of the best-filled classes at Manchester, and the competition was excellent. The Dark-feathered ones were unquestionably superior to the Light ones, and as most of our greatest breeders exhibited, the task of the Judges in these classes was a most difficult one. The *Polish* were very good, and so were the *Hamburghs*, the best of the latter classes being the Golden-spangled, and the worst the Silver-pencilled ones. Of *Game* fowls, although the majority of the old birds were wonderfully good, those of this year's production were, as they have been everywhere of late, not in good sound plumage. Of the *Game Bantams*, however, the classes were unexceptionably good. We never remember seeing better Aylesbury and Rouen *Ducks* than competed here, and in large numbers; the Buenos Ayrean Ducks were also very fine. The *Geese* and *Turkeys* were such as called forcibly to mind Christmas-tide, when, all temporary dissents forgotten, whole families join together in happy reunions; and single birds, like those shown at Manchester, varying from 27 lbs. to 33 lbs. each, are well adapted for such festive occasions.

In the class for Waterfowl there was a most extraordinary competition, Shovellers being first, Whistling Ducks second, and Mandarins third. Such an assemblage of fancy water fowls is but rarely seen, and numbers of pens well worthy of prizes had to be allotted high commendations. In this class were exhibited Sebastopol, Spanish, Spur-winged, Brent, and White-fronted Geese; whilst a very numerous entry of Teal, Widgeon, Pochards, Tufted-Ducks, Shell-Ducks, Carolinas, Pintails, and other varieties made this one of the most popular classes in the Show. French fowls were shown in good condition, and added no little interest to the collection. A pen of very good Cuckoo Cochins was exhibited.

In *Pigeons* the Manchester Show as usual was very strong, and the collection of "Any other variety" embraced several quite new breeds. We were sorry to hear that some of the Pigeons had been grossly tampered with, both as to colour and improved (?) characteristics; we were informed that had these particular birds been left untouched their success would have been unquestionable. As then treated they were very properly disqualified. When will exhibitors learn, that Nature unadorned will best carry the day with judges of experience?

DORKING (Coloured, except Silver-Grey).—*Cock.*—1, Mrs. F. S. Arkwright, Sutton Scarsdale, Chesterfield. 2, W. Harvey, Sheffield. 3, J. H. Fielden, Walsden. *hc*, R. Wood, jun., Clapton, Thrapstone; E. Leech, Rochdale. *Hens.*—1, Mrs. F. S. Arkwright. 2, G. Clarke, Long Sutton. 3, J. Copp'e, Eccleston, Prescot. *hc*, R. Wood, jun.; T. Statter, Stand, Manchester. *c*, W. Harvey. *Cockerel.*—1, Mrs. F. S. Arkwright. 2, J. Copple. 3, Hon. H. W. Fitzwilliam, Wentworth Woodhouse. *hc*, S. H. Stott, Rochdale; H. Crossley, Broomfield, Halifax; Mrs. F. S Arkwright; J. Copple; R. D. Holt, Orrest Head, Windermere; T. Statter. *c*, A. Darby, Bridgenorth; T. L. Jackson, Bush of Ewes, Langholm; E. Shaw, Plas Wilmot, Oswestry. *Pullets.*—1, Mrs. F. S. Arkwright. 2, T. Statter. 3, J. Copple. *hc*, T. L. Jackson; R. Wood, jun.; G. Hellewell, Walkley; Mrs. F. S. Arkwright. *c*, F. Schofield; J. Crutchloe, Oswestry; T. Statter; Hon. H. W. Fitzwilliam; Miss Milne; J. Martin, Claines, Worcester.

DORKING (Silver-Grey).—*Cock.*—1, J. Statter. 2, T. Raines, Stirling. 3, Miss Milne, Otterburn. *c*, D. Parsons, Cuerdon, Preston; R. Smalley, Lancaster. *Hens or Pullets.*—1, T. Statter. 2, T. Raines. 3, W. W. Ruttledge. *hc*, D. Parsons; R. D. Holt; R. Smalley.

DORKING (Rose-combed or any other variety).—1, J. Martin (Coloured Rose-combed). 2, Miss Fairhurst, Woodlands, Preston (White). *hc*, P. McDonald, Sale (White); D. Parsons (White); Miss Fairhurst (White).

SPANISH.—*Cock.*—1, W. R. Bull, Newport Pagnell. 2, Hon. Miss D. Pennant, Penrhyn Castle, Bangor. *hc*, C. W. Brierley, Middleton. *Hens.*—1, Hon. Miss D. Pennant. 2, C. W. Brierley. 3, Burch & Boulter, Sheffield. *hc*, H. Beldon, Goitstock, Bingley; J. Thresh, Bradford. *Cockerel.*—1, C. W. Brierley. 2, R. Teebay, Fulwood, Preston. 3, W. R. Bull. *hc*, R. Davies, Chester; R. Teebay; J. Thresh. *c*, Hon. Miss D. Pennant; R. Teebay. *Pullets.*—1 and 2, Hon. Miss D. Pennant. 3, Burch and Boulter. *hc*, R. Teebay; T. & E. Comber, Warrington; J. Walker.

COCHIN-CHINA (Cinnamon and Buff).—*Cock.*—1, H. Mapplebeck, Birmingham. 2, W. A. Burnell. 3, R. White, Shirebrook, Sheffield. *hc*, T. Stretch, Ormskirk; W. A. Taylor, Manchester; J. Sichel, Timperley; J. Poole, Ulverstone. *c*, J. Cattell; H. Mapplebeck; J. H. Dawes, Moseley Hall, Birmingham. *Hens.*—1, J. Cattell. 2, W. A. Burnell, Southwell, Notts. 3, J. Poole. *hc*, A. Darby; W. A. Taylor; R. White; J. Sichel; H. Mapplebeck. *Pullets.*—1, Mrs. A. Woodcock, Rearsby House, Leicester. 2, W. A. Taylor. 3, J. Sichel. *hc*, A. Darby; T. Stretch; C. Sidgwick; J. H. Dawes. *c*, W. A. Taylor; Mrs. A. Woodcock.

COCHIN-CHINA (Brown and Partridge-feathered).—*Cock.*—1, J. A. Taylor. 2, T. Stretch. 3, R. White. *hc*, T. Stretch; R. B. Wood; E. Tudman, Whitechurch. *c*, C. Sidgwick; H. Crossley; Miss Story, Derby. *Hens.*—1, J. A. Taylor. 2, E. Tudman. *hc*, T. Stretch; C. Sidgwick, Ryddlesden Hall, Keighley. *Pullets.*—1, J. Wood, Brinscall. 2, T. Stretch. 3, H. Lingwood. *hc*, J. A. Taylor; C. Sidgwick; J. Horrocks, Tonge. *c*, H. Crossley; J. H. Dawes; E. Tudman.

COCHIN-CHINA (White).—*Cock.*—1, R. Smalley, Lancaster. 2, Mrs. A. Williamson. *Hens or Pullets.*—1, R. Smalley. 2, R. Brown, Cheadle, Hulme. *hc*, Mrs. A. Williamson. *c*, Bowman & Fearon.

BRAHMA POOTRA (Dark).—*Cock.*—1, A. F. Hurt, Alderwasley, Derby. 2, Hon. Miss D. Pennant. 3, Rev. J. F. Newton, Kirby-in-Cleveland. *hc*, Rev. E. Alder, Etwall Vicarage, Derby; W. Wykes, Wolvey, Hinckley; E. Leech; Mrs. Bailey, Shooter's Hill, Longton; Mrs. A. Woodcock; J. H. Pickles, Earby; R. White; J. H. Dawes; A. F. Hurt. *c*, Rev. E. Alder, Etwall Vicarage, Derby; W. Gamon; R. White. *Hens or Pullets.*—1 and 2, A. F. Hurt. 3, H. Lingwood, Creeting, Needham Market. *hc*, Rev. E. Alder; H. Dowsett, Pleshey, Chelmsford; C. Layland; J. H. Pickles; A. F. Hurt; J. Anderson, Meigle, N B. *c*, W. Whiteley.

BRAHMA POOTRA (Light).—*Cock.*—1, H. Lacy, Hebden Bridge. 2, Mrs. A. Williamson. 3, J. Pares, Postford, Guildford. *hc*, F. Crook, Forest Hill. *Hens or Pullets.*—1, H. Dowsett. 2, F. Crook. 3, Mrs. A. Williamson. *hc*, H. Lacy. *c*, Rev. N. J. Ridley; W. Whiteley, Sheffield.

POLISH (Any variety).—*Cock.*—1, M. Nicholls, Peel, Isle of Man. 2 and 3, G. C. Adkins, Birmingham. *hc*, H. Beldon; W. Gamon, Chester; T. Dean, Keighley. *Hens or Pullets.*—1, G. C. Adkins. 2, H. Beldon. 3, W. Harvey. *hc*, G. C. Adkins; W. Gamon.

CRÈVE-CŒUR.—1, W. R. Park, Melrose. 2, W. Blinkhorn, Waterdale, St. Helen's. 3, C. Layland, Warrington. *hc*, W. Harvey. *c*, W. Blinkhorn; R. B. Wood.

HOUDANS.—1, L. Biney, Manchester. 2, C. Morris. *hc*, R. B. Wood; S. H. Stott.

GAME (Black-breasted Reds).—*Cock.*—1, J. Halsall, Ince. 2, G. Hellewell. 3, C. W. Brierley. *hc*, L. Biney; C. Chaloner, Whitwell, Chesterfield; T. Sharples. *Hens.*—1, J. Halsall. 2, J. Poole. *hc*, Capt. G. Price. *Cockerel.*—1, C. Chaloner. 2, W. E. Oakeley, Atherstone. 3, S. Matthew, Stowmarket. *Pullets.*—1, J. Holland, Northwich. 2, Capt. G. Price. 3, T. Mason, Green Ayre, Lancaster. *hc*, J. Duxberry, Bradford; T. P. Lyon, Knotty Ash, Liverpool. *c*, J. Duxberry; J. Holland.

GAME (Brown and other Reds, except Black-breasted).—*Cock.*—1 and 2, J. Wood. 3, T. Statter. *hc*, T. Mason; C. W. Brierley; F. Sales, Crowle. *Hen.*—1, C. W. Brierley. 2, J. Wood. *hc*, B. Consterdine, Brookfield, Littleborough; E. Mann, Stand, Manchester. *Cockerel.*—1, J. Wood. 2, T. Mason. 3, E. Aykroyd, Bradford. *hc*, J. Wood; W. Boulton, Dalton-in-Furness. *c*, Rev. F. Watson, Kelvedon. *Pullet.*—1 and 2, J. Wood. 3, W. Boulton. *hc*, T. Mason; J. Wood; C. W. Brierley.

GAME (Duckwings, and other Greys and Blues).—*Cock.*—1, S. Matthew. 2, C. W. Brierley. 3, C. Chaloner. *hc*, P. Norbury, Bowdon; F. Sales. *c*, J. Cooper, Birmingham; J. Crutchloe; W. J. Cope, Barnsley. *Cockerel.*—1, W. J. Cope. 2, C. Chaloner. 3, J. Holland. *hc*, P. Newbury. *Hens or Pullets.*—1, G. S. Sainsbury. 2, E. A. Johnson, Wath-upon-Dearne; E. A. Johnson; J. Halsall; J. Poole. *c*, W. J. Cope.

GAME (Any variety).—*Cock.*—1, G. & C. Furness, Accrington. 2, W. Gamon. *Hen or Pullet.*—1, P. Norbury. 2, J. Poole.

DUCKS (Rouen).—*Drake.*—1 and 2, T. Statter. 3, S. Cox, Stacksteeds. *hc*, D. Parsons; Gunson & Jefferson, Whitehaven; T. Statter. *c*, S. H. Stott; D. Hardie, Sorbie, Langholm; H. Crossley; W. Gamon; T. Burns; J. Anderson. *Ducks.*—1 and 2, W. Statter. 3, D. Hardie. *hc*, S. Cox; R. Gladstone, jun., Court Ley, Liverpool; T. Burns, Abram, Liverpool. *c*, T. Burns.

DUCKS (White Aylesbury).—1, 2, and 3, Mrs M. Seamons, Aylesbury.

DUCKS (East Indian).—1, S. Burn. 2, Rev. W. Serjeantson, Acton Burnell. *hc*, H. Lacy; S. Burn; Rev. W. Serjeantson; J. M. Kilvert, Ludlow.

WATER FOWL (Ornamental).—1, J. Jennison, Zoological Gardens, Manchester (Shovellers). 2, C. W. Brierley. 3, C. N. Baker, Chelsea (Mandarins). *hc*, J. Jennison (White-fronted Geese, Shieldrakes, Pintail, and Tufted Divers); H. Smvile, Ollerton (Sebastopol, Spanish, and Brent Geese); H. Mapplebeck; J. Knott, Kirkmanshulme (Spur-winged Geese); M. Leno, Markyate Street, Dunstable. *c*, J. Jennison (Widgeon); C. N. Baker (Carolinas); J. Knott (Pochard Divers).

GEESE (White).—*Gander.*—1, E. Leech. 2, T. Statter. 3, R. Gladstone. *hc*, W. Rostron, Levenshulme; Rev. G. Hustler, Stillingfleet Vicarage, York. *Geese.*—1, Rev. G. Hustler. 2, E. Leech. 3, W. Rostron. *hc*, J. N. Beasley; S. H. Stott; T. Statter.

GEESE (Grey and Mottled).—*Gander.*—1, H. Crossley. 2 and 3, E. Leech. *hc*, S. H. Stott; T. Statter. *c*, Rev. G. Hustler. *Geese.*—1, E. Leech. 2, J. Lycett. 3, Rev. G. Hustler. *hc*, S. H. Stott; H. Crossley; Rev. G. Hustler; T. Statter.

TURKEYS.—*Cock.*—1, J. Smith, Grantham. 2, Mrs. A. Guy, Eaton, Grantham. 3, W. S. Holden, Greenfield, Farnworth. *hc*, Rev. N. J. Ridley, Newbury. *c*, W. Wykes. *Hens.*—1, J. Smith, Grantham. 2, Mrs. A. Guy. 3, W. S. Holden. *hc*, S. H. Stott.

EXTRA STOCK.

ANY VARIETY.—1, Hon. C. W. Fitzwilliam (La Flèche). 2, G. & C. Furness (Cuckoo Cochins). *hc*, F. Hill & Co., Brigaton (Gangeslan). *c*, J. Goodwin, West Gorton (Malays).

HAMBURGHS (Black).—*Cock.*—1, N. Marlor, Denton. 2, W. Green. 3, Rev. W. Serjeantson. *hc*, D. Lord; J. M. Kilvert. *c*, Mason & Walker; J. Partington, Little Heaton. *Hens or Pullets.*—1, N. Marlor. 2, Rev. W. Serjeantson. 3, J. Garside, Shaithwaite. *hc*, Rev. W. Serjeantson; H. Mason; Mason & Walker, Denton, Manchester; J. Smith. *c*, S. Butfield, Keighley; W. Green.

HAMBURGHS (Golden-spangled).—*Cock.*—1, W. A. Hyde, Hurst, Ashton-under-Lyne. 2, T. Scholes, Hollinwood. 3, J. Roe, Hadfield. *hc*, J. Ogden. *c*, J. Buckley, Tannton, Ashton-under-Lyne; T. Scholes; N. Marlor; H. Mason. *Hens or Pullets.*—1 and 3, W. A. Hyde. 2, J. Buckley. *hc*, J. Buckley; T. Scholes; J. H. Howe, Denton; H. Mason.

HAMBURGHS (Silver-spangled).—*Cock.*—1, Ashton & Booth, Broadbottom, Mottram. 2, J. H. Howe. 3, H. Pickles, jun. *c*, J. Fielding, Newchurch, Manchester; Ashton & Booth. *Hens or Pullets.*—1, Ashton & Booth. 2, H. Pickles, jun. 3, J. Partington. *hc*, J. Fielding; J. H. Howe.

HAMBURGHS (Golden-pencilled).—*Cock.*—1, H. Beldon. 2, T. Wrigley, jun., Tonge. 3, G. Anderton. *hc*, S. Burn, Whitby; J. Smith, Manchester. *Hens or Pullets.*—1, H. Beldon. 2, J. Smith, Manchester. *hc*, W. R. Park; Burch & Boulter. *c*, S. Burn.

HAMBURGHS (Silver-pencilled).—*Cock.*—1, H. Pickles, jun. 2, H. Beldon. *hc*, J. Partington; Mrs. Allsopp, Hindlip Hall, Worcester. *c*, J. Smith, Manchester. *Hens or Pullets.*—1, H. Pickles, jun. 2, H. Beldon.

GAME BANTAMS (Black-breasted Reds).—*Cock.*—1, E. Hudson, Ulverstone. 2, W. F. Entwisle, Westfield, Cleckheaton. 3, J. Sumner, Upholland Moor, Wigan. 4, J. R. Robinson, Sunderland. *hc*, J. W. Morris, Rochdale; R. Gerrard, Chowbent; H. Ashton, Polefield Hall, Prestwich; J. Crosland, jun., Wakefield; T. Taylor, Kendal; G. & C. Furness; T. Sharples, Rawtenstall; J. Poole. *c*, H. Shumach; O. Heafford. *Hens or Pullets.*—1, W. F. Entwisle. 2, J. H. Howe. 3, H. J. Marsden. *hc*, J. W.

Morris; H. Ashton; G. Heafford, Loughborough; J. Crosland. *c*, J. W. Morris; J. Heaton.

Game Bantams (Any variety except Black-breasted Reds).—*Cock.*—1, W. Adams, St. Clements, Ipswich. 2, H. J. Nicholson, Holborn Hill, Cumberland. 3, Mason & Charlesworth, Chesterfield. *hc*, J. Crosland, jun.; G. & C. Furness; W. Gamon. *c*, T. Sharples, Accrington; G. Anderton. *Hens or Pullets.*—1, J. Crosland, jun. 2, J. Sichel. 3, Mason and Charlesworth. *hc*, L. Biney; Mason & Charlesworth; W. Adams.

Bantams (Any variety except Game).—1 and 3, M. Leno (Gold and Silver-laced). 2, J. A. Taylor, Manchester (Black Clean-legged). *hc*, J. W. Morris (Black Clean-legged); Mrs. Woodcock (White Japanese); H. Pickles, jun. (Black Clean-legged). *c*, C. N. Baker (Sennerat's Jungle Bantame.)

PIGEONS.

Pouters (Blue or Red).—*Cocks.*—1, R. Fulton, Deptford. 2, W. Gamon. *hc*, F. Crossley, Elland, Halifax. *Hens.*—1 and *hc*, R. Fulton. 2, F. Crossley.

Pouters (Any colour except Blue or Red).—*Cocks*—1, W. Harvey. 2, R. Fulton. *Hens.*—1 and 2, R. Fulton. *hc*, W. Harvey.

Carriers (Black).—*Cocks.*—1 and *c*, T. Colley, Sheffield. 2, J. Chadwick, Bolton. *vhc*, J. Thompson. Bingley. *hc*, R. Fulton. *Hens.*—1 and 2, R. Fulton. *hc* and *c*, F. Crossley.

Carriers (Dun).—*Cocks.*—1, J. Chadwick. 2, T. Colley. *vhc*, F. Crossley. *hc*, F. J. MacLaren, Highfield, Pendlebury. *Hens.*—1, W. MacLaren. 2, J. Thompson. *hc*, F. Crossley.

Carriers (Any colour except Blue or Dun).—*Cocks.*—1 and *vhc*, J. C. Ord, Pimlico, London. 2, R. Fulton. *Hens.*—1, A. Lowe, Over Hulton, Bolton. 2, R. Fulton. *hc*, J. C. Ord.

Dragoons (Yellow).—1, J. C. Ord. 2, G. South, London. *hc*, W. Gamon. *c*, H. Yardley.

Dragoons (Any other colour).—1, W. Harvey. 2, G. Smith. *hc*, A. Lowe; F. Hughes, Heavily, Stockport; J. J. Bradley, Birmingham. *c*, Mrs. F. S. Arkwright.

Antwerps.—1, J. J. Bradley. 2, H. Yardley, Birmingham. *vhc*, W. Harvey; Mrs. F. S. Arkwright.

Jacobins.—1 and 2, J. Thompson. *hc*, E. E. M. Royds.

Barbs.—1, J. Firth, Webster Hill, Dewsbury. 2, R. Fulton. *hc*, R. Fulton.

Fantails (White).—1 and *vhc*, C. Bulpin, Bridgewater. 2, J. Hawley, Bingley. *hc*, H. Yardley.

Fantails (Any colour except White).—1 and *vhc*, F. Graham, Birkenhead. 2, H. Yardley.

Tumblers (Almond).—1 and 2, R. Fulton. *hc*, J. Fielding, jun., Rochdale.

Beards or Balds.—1, G. South. 2, J. Fielding, jun. *hc*, R. Fulton. *c*, W. H. C. Oates.

Tumblers (Any variety not before named).—1, J. Fielding, jun. 2 and *hc*, R. Fulton.

Nuns.—1 and 2, W. Baukes, Runcorn. *hc*, F. Graham; J. Baily, jun., Mount Street, Grosvenor Square, London. *c*, F. Graham; H. Draycott, Humberstone, Leicester; J. Baily, jun.

Magpies.—1, P. H. Jones, Fulham. 2, J. Baily, jun. *hc*, C. Bulpin.

Turbits.—1, W. Baukes. 2, G. South. *vhc*, F. Graham; C. Bulpin. *hc*, R. Fulton. *c*, J. Fielding, jun.

Swallows.—1 and 2, J. Baily, jun.

Archangels.—1, C. Bulpin. 2, J. Thompson.

Owls (Blue and Silver English).—1, J. Goolden, Hale, Altrincham. 2, J. Firth, jun. *hc*, C. Bulpin. *c*, A. Jackson, Heaton, Bolton; J. Dyson, Altrincham; J. Dorrington, Didsbury.

Owls (Foreign).—1, J. Fielding, jun. 2, F. Crossley.

Runts.—1 and 2, T. D. Green, Saffron Walden. *vhc*, P. H. Jones. *hc*, H. Yardley.

Trumpeters.—1 and 2, J. Firth, jun. *vhc*, J. Hawley. *hc*, W. Harvey; W. H. C. Oates, Besthorpe, Newark.

Any other Variety not Before Named.—1, P. H. Jones (Florentines). 2, H. Yardley. 3, F. H. Paget, Birstall. *hc*, W. Harvey; H. Yardley (Satinettes); T. Haslam, West Gorton (Crested, Passenger, and American Wood); J. Baily, jun. (German Toy and Austrian Archangels). *c*, J. Baily, jun. (Isabels and Austrian Archangels).

Doves (Any variety).—1, 2, and *hc*, J. Jennison (Chinese, Mexican, White Turtle, and English Turtle Doves.)

Judges:—*Dorkings, Spanish, Cochins, French Breeds, Extra Stock, and Bantams, except Game:* Mr. Edward Hewitt, Sparkbrook, Birmingham. *Brahmas:* Messrs. Hewitt and Teebay. *Game and Game Bantams:* Mr. Richard Teehay, Fulwood, Preston. *Hamburghs, Polands, Ducks, &c.:* Mr. James Dixon, North Park, Bradford, Yorkshire. *Ornamental Waterfowls:* Messrs. Dixon and Hewitt. *Pigeons:* Mr. W. B. Tegetmeier, Finchley; Mr. T. H. Ridpeth, Ontwood Hall, Handforth.

WEST OF ENGLAND POULTRY SHOW.

This Show, held on the 13th, 14th, 15th, and 16th of December, at the Agricultural Hall, Plymouth, was in advance of any former Show, all the *Game* being especially good, the first-prize pen beating the first-prize Black Reds at Menheniot. The single cock first at Menheniot was again the winner here, and the owner was first last year also. *Dorkings* were better than we have ever seen before in the west. *Hamburghs* and *Bantams* were very good; in fact, all the classes, with the exception of the Malay, or the so-called Indian, and the cross-bred class, were very good.

Game (Black-breasted and other Reds).—1, W. T. Spearman, Redruth, 2, S. R. Higham, Morchard Bishop. 3, R. Cleave. *hc*, C. E. Brittain Plymouth. *c*, J. Collacott, Tavistock.

Game (Any other variety).—1, N. Barter, Plymouth. 2 and 3, R. Cleave.

Game (Any variety).—*Cock.*—1, J. Harris, Liskeard (Brown Red). 2, E. C. Pope, Falmouth (Brown Red). *c*, S. R. Higham (Duckwing).

Game (Indian).—1, T. White, Liskeard. 2, J. N. Jasper.

Dorking (Any variety.—1, W. S. Trevithick, Hayle. 2, W. Brown, Callington. 3, F. Seccombe, Totness. *c*, E. Elliott, Landulph.

Cochins (Buff, Cuckoo, or Partridge).—1, J. H. Nicholls, Lostwithiel. 2, W. L. Trewin, Stratton. 3, J. Beard, St. Blazey. *c*, T. E. Hawken, Lostwithiel.

Cochins (Cinnamon, White or Black).—1 and 2, F. Brewer, Lostwithiel.

Brahma (Light).—1, P. D. Maddox, Launceston. 2 and 3, F. Seccombe.

Brahmas (Dark).—1, R. W. Beachey, Kingskerswell. 2, J. H. Reed, Calstock. 3, S. J. Lampen, Hayle. *c*, E. Bennett, Plymouth.

Polands (Any variety).—1, J. Snow, Plympton. 2, J. Beard. 3, J. Hinton, Warminster.

Spanish.—1 and Cup, Tonkin & Tuckey. 2, J. H. Reid. 3, F. Brewer.

Hamburghs (Gold or Silver-pencilled).—1, N. Barter, Plymouth. 2, S. R. Harris, St. Day. 3, J. H. Nicholls. *hc*, J. Roberts, Menheniot. *c*, J. Beard.

Hamburghs (Gold or Silver-spangled).—1, J. Williams, Menheniot. 2 and 3, S. R. Harris.

Game Bantams.—1, W. Mudge, Paignton. 2, N. Barker. 3, F. Brewer. *c*, W. T. Serjeant, Callington.

Bantams (Any other variety).—1, N. Barter. 2, A. Hodson, Bridgewater. 3, W. T. Clark, Bristol. *hc*, T. E. Hawken.

Any other Distinct Variety.—1, J. H. Nicholls (Crève-Cœur). 2, F. Brewer (Houdans). *hc*, H. Francis, Stratton (Black Cornish). *c*, T. Sherston, Falmouth (Black Hamburghs); J. Snow, Plympton (Crève-Cœur).

Selling Class.—1, N. Davey Perranwell (Black Red Game). 2, S. R. Harris (Golden-pencilled). 3, S. Mitchell, Tavistock (Dark Brahma). *hc*, J. Medway, Newton Abbott (Golden-spangled Hamburghs); J. H. Nicholls (Black Red Game). *c*, W. J. Lamb, Devonport (Duckwing Game).

Mixed or Crossbreed.—1 and 3, Withheld. 2, H. Pike, Pennycross.

Any Variety except Game.—*Cock.*—1, J. H. Nicholls (Black Hamburghs). 2, W. L. Trewin (Partridge Cochin). 3, T. E. Hawken (Andalusian).

Ducks (Rouen).—1, 2, and 3, J. H. Hoit, St. Austell.

Ducks (White Aylesbury).—1, F. Seccombe. 2, J. H. Nicholls. 3, T. E. Hawken.

Ducks (Any other variety).—1, J. H. Nichols. 2, T. M. Medland.

Geese (Any variety).—1, J. H. Nicholls. 2, W. Smith, Exeter.

Turkeys (Any variety).—1, W. Smith.

Pigeons.—*Carriers.*—1, W. H. Oxland, Plymouth. 2, J. P. Bolt, Tavistock. *hc*, A. Court, Taunton. *c*, E. Burton, Truro. *Pouters.*—1, A. Court. 2, C. Bulpin. *Tumblers.*—1, J. P. Bolt. 2, T. Chudley, jun., Plymouth. *Fantails.*—1, E. Prideaux. 2, E. Burton. *Any other Variety.*—1, J. Chapple, Newton Abbott. 2, W. Mudge. *hc*, C. Bulpin. *c*, F. Brewer.

Judge.—Mr. J. K. Fowler, Willowbank, Aylesbury, Bucks.

WEST HERTS (WATFORD) POULTRY SHOW.

This has now been held for many years, in conjunction with a fat stock show, about a fortnight before Christmas. It is always a good Show, and with some alterations might become a very large one. Inducements are not wanting. Plate prizes were common, and a stand presided over by one of the employés of Messrs. Elkington was sufficiently tempting to induce everyone to become a subscriber. Everything was there, cups, candelabra, candlesticks, ordinary articles of domestic use, down to silver-mounted beer-horns, all for the good service of the successful exhibiters—an *embarras de richesses;* nothing being required in order to have a personal interest in the attractive Show but to be pre-eminent in poultry.

The Show was held in very large tents, the best found and best managed we have ever seen, perfectly dry and comfortable, spite of the driving rain and wind, and having the great boon of a well-boarded floor raised some inches above the grass, and covered with shingle and sawdust. The pens were in double tiers, but the bottom ones were sufficiently high to enable their occupants to be seen plainly without effort. There was also ample space to allow full and comfortable circulation.

We have never seen better *Dorkings* than those belonging to the Rev. E. Bartrum, of Berkhampstead, which deservedly took both prizes for Dorkings. Mr. Horsfall's Grouse *Cochins* brought him a piece of plate and two prizes. With the exception of this colour, Cochins do not seem to find favour in Hertfordshire. *Brahma Pootras* are favourites everywhere, and excellent pens were the result. Mr. Horsfall took the piece of plate, Mr. Barnes being second. The Light Brahmas were very weak in every respect. There were some good Golden-spangled and average Golden-pencilled *Hamburghs.* These classes want strengthening, but the restriction of the competition to one county makes that a difficult process. There was an excellent show of Game *Bantams*, Lord Chesham taking the first prize, Mr. Copeland the second. It is naturally expected that Sebright Bantams should be good in Hertfordshire, and they were worthy of their county. Lord Ebury showed excellent *Spanish*, and deservedly took the first prize. Mr. P. Jones's *Polands* were of high merit. We have had hitherto to do with chickens, but now we have a class of the highest possible character, pens full of most excellent birds, of which we shall speak hereafter. *Ducks* were strong in every way, numbers, weight, and quality. They left nothing to desire, and the cup Aylesburys of Lord Chesham deserved their accumulated honours. Beautiful Mandarin and Carolina Ducks were shown. Nothing could be better than the *Geese* and *Turkeys;* they were very heavy, and in faultless condition. We cannot avoid mention of some American Turkeys belonging to Lord Rokeby and Mr. Barnes, better than any we have seen for a long time. The *Pigeons* were a long success for Mr. Parkin Jones.

Dead poultry closed the exhibition — dead fowls, Ducks, Geese, and Turkeys. Three of these prizes went to Lord Chesham, one to the Earl of Essex. The specimens were very good.

This was one of those pleasant meetings where all are comparatively neighbours, and known to each other, and where all are directly interested in the success and well-doing of the Show. It has the advantage of making the Show a real promenade, but this pleasure is not without its purchase. A limit is put to a show where it is confined to

one county, not only in the number of birds shown, but in the amount of good it is to do. The greater the competition the greater the honour of success, and a small advantage will always belong to the home owner from the fact the birds have not to travel, and avoid the wear and tear, and fasting. This is enough to turn the scale in their favour.

We have here to mention the class for aged birds to which we referred. There were sixteen pens of the best birds in the Show sent to compete for two prizes among themselves, to the weakening of the Show generally. The difference between a bird of 1869 hatched in January, and one in 1868 hatched in August, or even June of that year, is very small, almost imperceptible, and it would be a great improvement if the classes were open to all ages. With competent judges there is no danger of disadvantage to any pen on account of age or otherwise.

Mr. Sedgwick was an indefatigable Secretary.

DORKINGS (Coloured).—1, Cup, and 2, Rev. E. Bartrum, Great Berkhampstead. *hc*, P. H. Jones, Fulham

DORKINGS (White).—2, Mrs King, Wiggenhall, Watford.

COCHINS (Partridge).—1, Prize for best pen of Cochin, 2, and *hc*, R. Horsfall, Watford. *c*, Mrs. King.

BRAHMA POOTRA (Dark).—1 and Prize for best pen of Brahmas, R. Horsfall. 2, C. A. Barnes, Chorleywood Farm, Rickmansworth.

BRAHMA POOTRA (Light).—2, Lord Chesham, Latimers, Chesham.

GAME (Any variety).—1, Lord Chesham (Black-breasted Red).

HAMBURGHS.—*Gold-pencilled.*—2, Miss Gee, Abbot's Langley. *Gold-spangled.*—1, Rev. R. L. James, Watford. *Silver-spangled.*—1, E. Moon, Watford. 2, W. J. Loyd, Langleybury.

GAME BANTAMS.—1, Lord Chesham. 2, W. F. M. Copeland, Watford. *hc*, C. A. Barnes; M. Leno, Markyate Street, Dunstable.

BANTAMS (Any other variety).—1, M. Leno (Gold-laced). 2, J. Davis, Hemel Hempstead (Japanese).

CRÈVE-CŒURS.—1, C. A. Barnes. 2, Dr. A. T. Brett, Watford.

ANY OTHER BREED.—1, Lord Ebury, Moor Park, Rickmansworth (Black Spanish). 2, P. H. Jones, Fulham.

ANY BREED.—1, Rev. R. Bartrum (Coloured Dorkings). 2, C. A. Barnes (Brahma Pootra). *hc*, Rev. E. Bartram (Coloured Dorkings); A. J. Copeland, Upper Nascott, Watford (Dark Brahmas); P. H. Jones (Polands and Spanish).

DUCKS (Aylesbury).—1 and Prize for best pen of Ducks, Lord Chesham, 2 and *hc*, C. A. Barnes. *c*, C. Longman, Shendish, Hemel Hempstead.

DUCKS (Rouen).—1, W. F. M. Copeland. 2, E. Moon. *hc*, M. Leno.

DUCKS (East Indian).—1, Mrs. King. 2, Miss Gee.

DUCKS (Any other distinct breed).—1 and 2, M. Leno (Mandarin and Carolina).

GEESE.—1 and Cup, T. Peramor, Aldenham. 2, C. A. Barnes. *hc*, J. H. Barnes; M. A. & F. J. Sedgwick, Hunton Bridge Farm, Watford.

TURKEYS (Any variety).—1 and Cup, C. Longman. 2, J. H. Barnes. *hc*, C. A. Barnes; J. H. Barnes; Lord Chesham; Lord Rokeby, Hazelwood, Watford.

PIGEONS.—*Carriers.*—1 and 2, P. H. Jones. *Pouters.*—1 and 2, P. H. Jones. *Tumblers* (Almond).—1 and 2, P. H. Jones. *Fantails.*—1 and 2, P. H. Jones. *Any other Variety.*—1, P. H. Jones (Jacobins). 2, C. Waghorn, Nether Wylde, St. Alban's (Trumpeters).

JUDGES.—Mr. J. Baily, 113, Mount Street, Grosvenor Square; Mr. G. Botham, Wrexham Court, Slough; and Mr. E. Hewitt, Sparkbrook, near Birmingham.

NORTH BRITISH COLUMBARIAN SHOW.

As we cannot in our present issue adequately notice this important Exhibition, we reserve our report for the next number, in the meantime recording a success as well-earned as it was interesting in the department of Ponters—the great speciality of our northern fanciers—and directing our readers to the annexed list of prizes.

MEMBERS ONLY.—(BIRDS BRED IN 1869).

POUTERS (Black).—*Cocks.*—1 and 3, G. Ure, Dundee. 2, J. Montgomery, Belfast. *Hens.*—1 and 3, J. Montgomery. 2 and *hc*, J. Huie.

POUTERS (White).—*Cocks.*—1 and 2, M. Sanderson, Edinburgh. 3 and *hc*, M. Stuart, Glasgow. *c*, J. Wallace, Burnbank, Glasgow. *Hens.*—1, G. Ure. 2, J. Montgomery. 3, M. Sanderson. *hc*, J. Wallace. *c*, W. R. Rose, Kettering.

POUTERS (Blue).—*Cocks.*—1, G. Ure. 2, J. Huie. 3, J. Montgomery. *hc*, M. Sanderson. *c*, J. Grant, *Hens.*—1, W. R. Rose. 2, J. Millar, Glasgow. 3, *hc*, and *c*, J. Montgomery.

POUTERS (Red).—*Cocks.*—1 and *hc*, W. R. Rose. 2, D. Stewart, Perth. 3, J. Montgomery. *c*, M Stuart. *Hens.*—1, J. Montgomery. 2, A. Frame, Larkhall. 3, *hc*, and *c*, W. R. Rose.

POUTERS (Yellow).—*Cocks.*—1, G. Ure. 2 and 3, W. R. Rose. *Hens.*—1, G. Ure. 2, J. Montgomery. 3, J. Wallace.

POUTERS (Mealy-barred).—*Cocks.*—1 and 2, J. Millar. 3, M. Sanderson. *Hens.*—1, J. Montgomery

CARRIERS (Black).—1 and 3, G. C. Holt, Lawton, Cheshire. 2 and *hc*, J. Wallace. *c*, G. A. Wherland, Cork.

BARBS.—1, 2, and 3, J. H. Framo, Overton. *hc*, J. Montgomery.

TUMBLERS.—1 and 2, J. Wallace.

OPEN CLASSES.

POUTERS (Black).—*Cocks.*—1 and Medal for the best Pied Ponter Cock, any colour, in the Show, J. Huie. 2, J. Montgomery. 3 and *c*, W. Volckman, London. *hc*, J. Millar. *Hens.*—1 and *hc*, W. Volckman. 2, A. H. Stewart. 3, J. Millar. *c*, J. Montgomery.

POUTERS (White).—*Cocks.*—1, D. Stewart. 2, G. Ure. 3, J. Wallace. *hc*, J. Montgomery. *c*, J. Huie. *Hens.*—1, G. Ure. 2, J. Ruthven. 3 and *hc*, W. Volckman. *c*, J. Bruce, Dunfermline.

POUTERS (Blue).—*Cocks.*—1 and *hc*, J. Montgomery. 2, J. Cochrane, Glasgow. 3, J. Millar. *c*, R. Arbuckle. *Hens.*—1, J. Millar. 2, J. Wallace. 3, G. Ure. *hc*, J. Montgomery. *c*, W. Meff.

POUTERS (Red).—*Cocks.*—1, 2, 3, and *hc*, J. Montgomery. *c*, J. Wallace. *Hens.*—1, W. Volckman. 2, 3, and *hc*, J. Montgomery. *c*, W. R. Rose.

POUTERS (Yellow).—*Cocks.*—1 and *hc*, J. Montgomery. 2, J. Ruthven. 3 and *c*, W. Volckman. *Hens.*—1 and Medal for best Ponter hen in the Pied classes, J. Montgomery. 2, W. Volckman. 3, M. Stuart. *hc* and *c*, J. Wallace.

POUTERS (Mealy-barred).—*Cocks.*—1, W. Volckman. 2, J. Millar. 3, R. Arbuckle, Glasgow. *hc* and *c*, J. Montgomery. *Hens.*—1, J. Grant, Edinburgh. 2, J. Montgomery. 3, W. R. Rose. *hc*, J. Waddell, Dumfries. *c*, W. Volckman.

POUTERS (Irregular in colour and marking).—*Cocks.*—1 and *hc*, J. Montgomery (Splash and Checker). 2, M. Stuart. 3, J. Ruthven, Glasgow. *c*, W. Volckman (Sandy). *Hens.*—1, J. Cochrane, Glasgow. 2, J. Wallace. 3, J. Bruce (Checker). *hc*, J. Montgomery (Splash). *c*, W. Volckman.

CARRIERS (Black).—*Cocks.*—1 and Medal for best Carrier Cock, J. C. Ord, Pimlico. 2, G. Wherland, Cork. 3, G. C. Holt. *hc* and *c*, J. Wallace. *Hens.*—1 and Medal for the best Carrier Hen, G. C. Holt. 2, J. Ruthven. 3 and *c*, J. Wallace. *hc*, J. C. Ord.

CARRIERS (Dun).—*Cocks.*—1, J. C. Ord. 2, J. Smith, Sunderland. *Hens.* 1, J. C. Holt. 2, J. Wallace. 3, J. C. Ord.

CARRIERS (Any colour, Black and Dun excepted).—1, 2, and 3, J. C. Ord.

ALMONDS (Short-faced).—1 and Medal for best pair of Short-faced, F. Graham, Birkenhead. 2, P. H. Jones. 3, J. Huie.

SHORT-FACED (Mottled or Self-coloured).—1, F. Graham (Mottled). 2, J. Fielding, Rochdale. 3, P. H. Jones.

BARBS (Black).—1 and Medal for best pair of Barbs, J. Montgomery. 2, P. H. Jones. 3, W. Meff, Aberdeen.

BARBS (Any colour, Black excepted).—1, G. A. Wherland, Cork. 2, J. Montgomery. 3, P. H. Jones.

FANTAILS.—1, 2, and Medal for best pair of Fantails, J. Sharpe, Johnstone. 2, A. H. Stewart. *hc*, W. Hendry, Aberdeen. *c*, A. Frame.

JACOBINS (Red and Yellow).—1, J. Sharp. 2, E. E. M. Royds, Rochdale. 3, J. Waddell. *hc*, J. R. Rennards. *c*, F. Graham.

JACOBINS (White and Black).—1, 2, and Medal for the best pair of Jacobins, E. E. M. Royds. 3, P. H. Jones.

TRUMPETERS (Black).—1, 2, 3, *hc*, *c*, and Medal for the best pair of Trumpeters, J. Montgomery.

TRUMPETERS (White).—1, W. H. C. Oates. 2, P. H. Jones.

TRUMPETERS (Mottled).—1, 2, 3, and *c*, J. Montgomery. *hc*, C. Campbell.

TURBITS.—1, 3, and Medal for the best pair of Turbits, P. H. Jones. 2, W. Banker, Runcorn. *hc* and *c*, H. L. Tivy, Cork.

OWLS (English).—1 and Medal for best pair of English Owls, P. H. Jones. 2, Miss Grange. 3 and *hc*, J. Ruthven. *c*, J. Wallace.

OWLS (Foreign).—1 and Medal for the best pair of Foreign Owls, J. Fielding, jun. 2, P. H. Jones. 3, W. Goddart.

NUNS.—1, H. Yardley. 2, W. Banker. 3, Miss E. M. Beveridge, Ayr. *hc*, P. H. Jones. *c*, F. Graham.

TUMBLERS (Beards, Balds, and Common).—1, W. H. C. Oates. 2, J. Fielding, jun. 3, F. Graham.

ANTWERPS.—1, J. J. Bradley, Birmingham (Cock imported from Belgium. Hen flew from London Bridge to Birmingham in three hours five minutes). 2 and 3, J. Ruthven.

DRAGOONS.—1, J. C. Ord. 2, J. Stewart. 3, H. Yardley, Birmingham. *hc*, J. Ruthven. *c*, P. H. Jones.

FANCY PIGEONS (Not otherwise classed).—1, W. Goddart (Black Austrian Ponter). Extra 1, 2, and 3, J. Wallace (Damascenes, Lace Fantails, and Abyssinian). Extra 2, H. Yardley (Satinettes). 3, J. Sharp.

JUDGES.—Frederick Esquilant, Esq., London; E. L. Corker, Esq., Croydon.

SKY TUMBLERS.

I FELT inclined to write a few words on this subject when your first article appeared, but I considered that somebody would take the subject up. However, as "READER" has not found Sky Tumblers, and asks for a finger-post, I will say my say.

What I understand by a Sky Tumbler is a bird that will fly high and long, and tumble more or less in its flight. In describing Sky Tumblers, I do not include those feather-legged, broken baldpate-looking Pigeons called sometimes "Birmingham Rollers;" but the clean-legged, broad-chested, shortish-beaked, compact, strong little bird known as the common Tumbler. I believe I have the very breed. At all events, I have as good birds of this type as I have been able to find, and I have been interested in Tumblers for years.

I have certainly heard of Tumblers which, if I could find out where they are, would put mine far in the shade—Tumblers which (so it is said) will fly in the sky from four to five hours; but though I have walked many miles, from time to time, to witness this feat, I have never yet seen it performed, and I have now learned to take such statements with a "grain of salt." If anybody has Tumblers which will "do" four to five hours day by day, or one day, unless they happen to be lost, and even then I should doubt their keeping on the wing all the time—I say if anybody will let me know where such may be seen to do it, I shall be glad of the information. I have known selected birds fly an hour, or a little more. Half an hour is not bad; three-quarters I should call good flying. In saying this, I do not allow any forced work.

How long these pretty little creatures might be made to keep on the wing after they had had their voluntary flight, by pelting them with stones, or firing off a gun, I have not had the cruelty to try. My birds go up of themselves, exulting in the privilege, and settle when they like—always at home. They are let out once a-day, occasionally twice. Some tumble

excessively, and these, as a rule, do not care to fly long; others tumble less frequently, and are fonder of flying. When I want to have very lofty soaring, I do not allow the excessive tumblers to take part in the excursion. In this case the birds rise to a great height, especially if there is a clear sky, and not much wind. The length of time Tumblers will remain at the extraordinary height to which they frequently rise seems to me to depend, without going into the consideration of that accumulative disposition and power which we call breed, on the weather, the way they are allowed to take exercise, food, the place in which they are kept, and the humour they happen to be in when allowed to leave their loft, for the best treatment cannot insure their flying equally well at all times.

My birds have never had any special attention further than seeing that they had clean water, good ventilation, good tares, plenty of grit, a lump of salt, and a bath now and then. In the summer I frequently give them their liberty all day, and though this is contrary to rule, I find they will often fly quite as high and as long as when they are confined for a great part of the day.

In colour my birds are mostly splashed—black-splashed, cinnamon-splashed, with rarely a whole-coloured bird; indeed, I do not recollect ever having a high flyer whole-coloured, though I have had plenty of low-flying specimens. Colour is, however, so very accidental, to use an unscientific word, that I should not be surprised to see any colour from my stock of birds.

I doubt not "Reader" would find good birds in Manchester, Macclesfield, or Chester; but if I might be pardoned for offering a little gratuitous advice in the matter, I should say, Do not buy from hearssy, but see the birds do what you want them to do. In matters of "fancy" a person is so often infatuated himself, that there is no wonder he should misrepresent.—Old Bob Ridley.

APIARIAN NOTES.

Ligurianising.—All my attempts to establish the Italian race in my apiary have resulted in total failure. I commenced the year with five stocks, two with pure, one with a "doubtful," and two with black queens; I received a very fine queen from Mr. Woodbury in November, 1868, and although it was very cold and frosty at the time, I managed to introduce her to a good stock safely, and was pleased to find on the first day I could venture to open the hive afterwards that she had commenced egg-laying, even at that inclement season.

In January the weather was very mild, primroses in bloom on the 17th, and crocuses on the 29th. In February the weather was more like April, and on the 4th and 5th the bees were out in droves, and I observed pollen carried in for the first time. I found only a handful of bees in No. 6; the queen, a pure one, was alive but very weak. I put in a bar of comb from a black stock with the adhering bees to strengthen them, but they did not seem to like the Italian queen, and next day I found her on the ground in front of the hive. I placed her on a comb amongst the bees, but they paid no attention to her, and the stock soon perished. "Fearing all was not right with the stock to which I had joined the Italian queen in November, I took off the top, and was agreeably surprised to find the bees busy rearing young. Many Ligurians had been bred since the queen's arrival, some were cutting their way out of the combs, and the queen was in splendid condition, and such a fine one!" So I wrote at the time, but, alas! how soon a change for the worse came over them. After the fine and mild weather of February, March set in cold and winterly, and all the stocks which seemed prosperous at the beginning proved to be sadly decimated and weakened at the end. Dysentery set in, and I feared my beautiful queen and all her subjects would die. I at once removed them into a clean new hive, thoroughly cleansed the floor-board, and removed all the dead every few days, and to strengthen them a little I added a comb, with the bees on, from the next stock. On the 3rd of April they seemed better, and the queen had recommenced laying. As I had also lost one of my black stocks, I purchased one from the country, very strong and heavy, in one of the old-fashioned straw skeps, thinking it would prove useful in Ligurianising.

April 11th, a glorious day, more like June. I tried to effect an exchange of queens, as the stock with the Italian queen was very weak; but, as Mr. Woodbury surmised, I found the bees in No. 5, from which I had removed the pure queen, so irascible on my presenting the black queen, that I thought it best to return them and trust to raising queens artificially. The black queen had a foot taken off in rescuing her from a worker. On the 19th I found a royal cell commenced in this hive (No. 10), and a grub in it, so I concluded the queen had either been slain for her temporary absence, or because she had lost a foot, or she had been stung in the attempt to transfer her. I excised the royal cell, and placed a bar of brood comb from the pure stock in its place. I also placed the pure queen in a nucleus box with all her attendants, and added a brood comb from another stock, thinking they would be warmer, and thrive better. On the 22nd I found three royal cells commenced on the Ligurian comb, and one tenanted by a grub two or three days old. I took out the comb, and gave the pure queen to this stock instead. They took to her rather suspiciously, and encased her for a few hours, but I found her at liberty in the evening. I took the comb with the royal cells, and placed it and the others from the nucleus with the bees in No. 9, and then placed them upon the stand of the old straw stock, and removed it to a new stand. On the 23rd the pure queen was busy laying, and the bees in the artificial swarm were very numerous, and attending carefully to the royal embryo. They had made several pieces of new comb already. On the 30th I found two royal cells on one comb in the swarm, and one royal cell upon another; so I placed the latter in a nucleus box with the adhering bees, and then set it on the stand of the straw stock, and removed it to another. On the 5th of May I found both queens at liberty in the artificial swarms. A few days afterwards I formed another by taking a brood comb from the pure stock, placing it in a nucleus box, and then on the stand occupied by the straw stock, removing the latter again to a new stand. The last swarm never reared a queen, and perished.

About this time I began to fear my queens thus reared artificially would not be fertilised, and that I should have nothing but drone-breeders. However, on the 4th of June I found lots of eggs in one of the hives. This queen continued laying fast for about a fortnight, and I was congratulating myself on my success; but on the 18th or 19th I fancied they were not right, so I examined the hive and could not find the queen either in the hive or out of it, but I found three or four royal cells formed, one sealed and others in progress. I looked again on the 20th but could not find her, and cannot form any idea what became of her; and although I removed the royal cells, and gave the bees a brood comb from the pure stock, they never raised another queen, though very strong at the time, and eventually they dwindled away until none were left. The royal cells taken from the last I gave to an artificial swarm; this raised a queen but I never saw her, the cell was empty, but no queen could be found; and either from the age of the bees, or from fighting, although they were 6 or 7 feet from any other hive, one-half of them must have died, the ground all around being strewn with the dead.

On the 6th of June, the queen in one of the first swarms had not been rendered fertile as there was no sign of eggs or brood, so I took about sixty drones in a glass to the hive, and then the queen was taken out upon a comb and set off for a flight, the doorway blockaded, and the drones set at liberty. She was soon back on the alighting board, but was sent off again several times, until I found some of the workers attacking her when she alighted, and fearing they might kill her I allowed her to enter. On the 8th of June I found a few eggs, so it seems she had met with a drone on the 6th; judging from these facts she must have been thirty-one or thirty-two days old at least before she became fertile, as I saw her first on the 5th of May. This swarm never prospered, and was afterwards joined to another, but in September all died.

On the 20th of June, although I had made three or four artificial swarms from the old straw stock, on going into the garden about four o'clock I observed in a pear tree what I at first took for a piece of matting, but on looking again I found it was a large swarm of bees; of course I had them hived as quickly as possible, and in ten or twelve days they had nearly filled a Woodbury hive with comb, and as I feared they would cast off a virgin swarm I placed a super on, but they never worked in it—the honey season here seemed to be over. The "old straw" must have had a wonderfully prolific queen, as the number of bees I took from it was immense, and on the 30th they seemed ready to swarm again. I had heard "piping" the last two days. They came out in numbers several times, but I could not watch them, so I drove them out, and placed them in a Woodbury hive on their old stand, and swept the bees from the artificial swarm above mentioned into the straw hive,

thinking they would make a fair swarm, and that they would prosper with the store of honey still left in the hive. However, they were afterwards attacked by robbers, and all cleaned out. All my artificial swarms came to grief, and on the 24th of October I found my beautiful Italian queen and nearly all the bees dead; only a few hundreds in the hive altogether, and not more than thirty or forty alive. Since then my "doubtful" stock has become emptied in some singular manner—I fancy they must have found a better home—and thus ends my attempts, extending over three seasons, at Ligurianising an apiary.

Cork Hives.—I have made one of these by way of experiment, and I find that last winter the bees were kept free from damp and disease, and were very strong, in fact it was my best hive. Such hives are very easy to make. Let a wooden frame be made just the same as for a straw Woodbury hive, and then have pieces of common cork cut the size of the openings (where the straw is placed in the others), and fit them in; then drive one or two wooden pegs in on each side to keep the cork in its place. For the top it is better to drive two pieces of strong wire edgewise through the frame and the cork to prevent it sinking in the middle with the weight of the feeding bottle, then cut a 2-inch hole through the centre, and the hive is complete. The pieces of cork for the sides cost 6*d.* each, and for the tops 1*s.* 6*d.*; so the whole hive can be made for a few shillings.

Remedy for the Sting of a Bee.—With all deference to Mr. Woodbury, I say, Use vinegar. Perhaps his cuticle is not so sensitive as mine and many other people's. Our milkman, for instance, was stung on his nasal organ, and for two or three days he could not see anything straight before him. Vinegar is handy, easily applied, alleviates the pain, and prevents swelling if applied immediately; it is really a comfort to have it ready in case your children get stung, as the sting being extracted and the vinegar applied to the wound, their tears are dried up, and your feelings are at rest at once. "Whatever's that?" exclaimed one of them one day as we were quizzing a large ichneumon fly through a magnifier. "His antennæ to be sure." "His antennæ! why, they are as big as mine." "Why," rejoined another young hopeful, "he means his Aunt Hannah!"—J. R. J.

ORIGIN OF THE HIMALAYAN RABBIT.

Its true origin (and curious enough it is) may be found in Darwin's "Animals and Plants Under Domestication." The account there is taken principally from your Journal for 1857, and differs entirely from Mr. Rayson's. It is, in brief, a cross between Silver-Greys and Chinchillas; and its name may be classed with such as "Archangel" Pigeons, "Brahma Pootra" fowls, "Labrador" Ducks, &c—names well-sounding enough, but only given in order to sell the animals.—Duckwing.

OUR LETTER BOX.

Books (*J. S. W.*).—"The Poultry-Keepers' Manual" contains what you need. You can have it free by post from our office if you enclose 7*s.* 10*d.* in postage stamps with your address.

Game Bantams' Eggs (*G. W. W.*).—They are quite as good as any other fowl's eggs for table use. You must not expect "the cheapest" book to be "the best." You can have post free from our office "The Poultry Book for the Many," if you enclose seven postage stamps with your address. "The Poultry-keepers' Manual" you can similarly have if you enclose 7*s.* 10*d.*

Swelled Crops (*Guildford*).—Give each bird a dessert-spoonful of gin daily until the crop becomes natural. We applied in vain for a prize list.

Hamburgh Cockerel's Eye (*Hants Henwife*).—We should attribute the loss of the eye to disease of some sort. It would not be roup, as in that case, though the face and lid are swollen, the eye remains perfect. There is a disease to which Spanish are subject which destroys the eye; that is incurable. We believe that is always the case where the eye—that is, the eyeball, is attacked. It is always advisable where an eyelid is swollen to treat it with cold water and vinegar.

Brahma Cock's Leg Inflamed (*Idem*).—No doubt he picks his legs because there is fever and they itch. Keep them well and constantly moistened with sulphur ointment till the feathers are grown and formed.

Ducks for One Drake (*B.*).—Six Ducks are too many for this season of the year. Three are enough. In three months' time he may have six. If your Ducks are old have a young drake; if they are young, have a two-year-old drake.

Yards of Dorkings (*Idem*).—Breed from your cup cock and the four heaviest and best-shaped hens you have. Divide the other hens and pullets between the two young cocks. It is, however, useless at this time of year to give them more than four or six each. There is no objection to their running together; but if you intend to hatch the eggs you must only use the eggs of certain hens and pullets.

Drinking Fountain—Cock's Spine Injured (*Chemicus*).—Use Baily's registered fountain. We should not breed from an injured cock.

Buckwheat—Cooked Meat (*Francis*).—You can buy buckwheat of any seed and corn dealer. If you wish them to lay early you will find raw meat a greater stimulant than cooked. The use of it is injurious to the birds.

Pullet Walking with Difficulty (*M. W.*).—The bird is probably injured in the spine; if it is not, it is suffering from atrophy, and will surely die. We do not think it is worth doctoring.

Golden-pencilled Hamburghs (*Subscriber, H. S.*).—The unfavourable state of the weather may well explain why your fowls are not in first-rate condition. They suffer from the constant rain and damp, and from boisterous and cold winds. If you look at your birds you will see them crouched under the shelter of a wall instead of running about in search of food. We do not much admire your feeding. We have never found fowls do well on Indian meal; they do not like it with us. A better feeding will be barleymeal or ground oats in the morning, some Indian corn at midday, and meal again in the evening. You need not breed from two or three sorts, but to breed prizetakers you must breed from two strains. It is almost impossible to breed first-prize cocks and pullets from the same birds.

Spanish Fowls (*H. Jones*).—They require feeding like any other fowls Good barley is good food. A little Indian corn is a good change; but the best and principal food should be barleymeal or ground oats. When preparing for exhibition many amateurs give a few white peas two or three times per week.

Feathers (*E. Jones*).—The feathers you send only tell us the colour of your birds. They are Cuckoos. There are Dorkings, and Malays, and Cochins of the colour. We fancy very likely these are four toed Cuckoo Dorkings.

Preserving Eggs in Lime (*Harriett*).—We have preserved eggs for many years in the way we recommended to you. The lime is always kept mixed in readiness, but not with the idea any good would result from it. We do not find the shells crack, nor does the inside mingle. We eat them constantly for breakfast. The most important point in preserving them in this way is to put them in when they are very fresh.

Carrier Pigeon's Eyes Diseased (*R. de Winton*).—In the earliest stage we would advise a lotion of alum and water. A lotion of lunar caustic (a skilful chemist would know the strength), has also been recommended. The disease is supposed to arise from the great development of wattle, and the tendency in old birds to the formation of spouts by the turning out of the lower lid. These spouts may be removed by being cut from below upwards with a pair of very sharp scissors.

Roup in Pigeons (*John Robinson*).—You say you have tried everything you have been told or read about with little success. A shrewd writer observed, "If I were a physician I should look not so much at symptoms as causes." So in Pigeon diseases. How about the loft—is it cold? is it draughty? is there any damp? does the rain drive in? do trees overshadow it? is the manure left on the floor? and is that floor of brick or wood? Pigeons will bear almost any amount of heat. We have had no illness in a ceiled loft which in summer is intensely hot, but cold or wet fancy Pigeons cannot bear. As you have tried the received remedies it is of no use detailing them. Again we say, Look to the cause, for cause there must be.

Fertilising Turkeys' Eggs (*A Six-years Subscriber*).—Yes, the whole of the eggs will be fertile without the hen being with the male bird again.

Ashford Poultry Show.—Mr. H. Dowsett writes to say, that it was he, and not Mr. Herbert, who gained the cup, first, and commended for Dark Brahmas.

Tredegar Poultry Show.—In the class of Dark Brahma Pootras, Mr. W. Sims, Stroud, had a pen "very highly commended."

Menheniot Poultry Show.—The first prize for Brown Red cocks, we are informed, was awarded to Mr. John Davies, of Moorswater Lodge, and not to Mr. S. R. Harris as stated in the prize list published page 467.

Pigeon Lice (*A. L.*).—The sheep ointment and blue unction are the same as the mercurial ointment sold by chemists. We should think sulphur ointment would be as effectual.

Hen Canary Singing (*A Six-years Subscriber*).—There is no reason why it should interfere with her breeding.

Waxbills (*L. B.*).—There are about six varieties of Waxbills. They are natives of Africa, Australia, and the island of St. Helena. The smallest variety is the Zebra, but which is the handsomest depends on fancy. The Zebra is handsomely marked, and that and the Orange-cheeked are the most rare. The food should be French and India millet and Canary seed. We are not aware of any foreign cage bird being smaller than the Waxbills.

Austrian Loan, &c. (*Inquirer*).—We know nothing about it. The best food for dogs is barley meal made into a paste with pot liquor or milk. Give a dessert-spoonful of flowers of sulphur daily until the eruption passes away. It will go more quickly if mild sulphur ointment be rubbed into the eruptions.

POULTRY MARKET.—December 22.

We are sorry we cannot report that the approach of Christmas has done anything towards infusing life into our market on trade. We can only chronicle a great stagnation at the time we go to press. We are unable to report on Turkeys.

5	W		41.4	27.3	34.4	16	8 8	4 4	20 10	0 8	3	5 42	5

From observations taken near London during the last forty-three years, the average day temperature of the week is 42.7°; and its night temperature 29.9°. The greatest heat was 57°, on the 3rd, 1860; and the lowest cold 11° below zero, on the 4th, 1867. The greatest fall of rain was 0.86 inch.

WHAT ARE YOU DOING THESE WINTER EVENINGS?

LET everyone of us answer that question to himself—it will do us good—it is a question put by a sound practical gardener in a letter with which these notes will conclude; and we would offer a few relative suggestions to all who read these pages. Let readers peruse them teachably; let contributors enrich them liberally; let the Editors preside over them kindly. Above all, let everyone of us, after acceding to those suggestions, take a lesson from one of near threescore and ten, who sometimes contributes to "our Journal." He was at his fireside table, had just concluded writing to us, and his hand was then on his Bible. Looking at his visitor he observed, pointing to a volume by his side, "I have just done with that book, and am going to finish the evening with the best." Such a man knows well what to do with his winter evenings, and all who follow his example will pass that most welcome of seasons—a peace-abounding Christmas. Such a season heartily do we wish to all friends round our Journal, and to none more heartily than to those addressed as follows:—

A CHAPTER FOR YOUNG GARDENERS.

"The evenings of winter are once more upon us, and very welcome they are to us gardeners, even if they do add somewhat to the care and anxiety inseparable from our calling. Very welcome and very precious to us is the time which these long hours of darkness place at our disposal; many studies to which but little attention has been given during the busier period of the year are now again taken up in downright earnest, and as progress is made towards that proficiency which is ever the reward of steady persevering application, the time that can be devoted to study even appears too short and precious for its purpose. No one can fully understand or realise this feeling unless he has experienced this longing for improvement. The old schoolboy couplet—

> 'He that in writing would improve,
> Must first with writing fall in love,'

is justly applicable to the would-be student of any branch of science or learning. Let a person of sufficient intelligence but devote himself to the acquisition of knowledge, perseveringly and steadily—aye, even a plodder if you will, who, instead of being daunted by a difficulty or failure, feels it but an incentive to increased exertion, and there need be no fear as to the result.

"As a practical application of this reasoning I would ask those young men who aspire to the charge of a garden, What are you doing with your winter evenings? and in asking this question I do not forget the difficulties in the way of such young men in the pursuit of knowledge. An isolated position is, generally speaking, one of the trials of a young gardener; it is but seldom he is situated near enough to a large town where he might obtain any of the advantages to be gained from good lectures, evening classes, and the like. Although, considered in such a sense, isolation is a drawback, yet the very quietness of the life, the being thrown back upon one's own resources, not unfrequently proves an advantage, causing us to cherish a feeling of self-reliance, and a spirit of self-help. Let a gardener but become engrossed with his business, striving constantly to excel, placing his standard of excellence very high, never suffering a failure to daunt him, but bending all his powers of mind and body to overcome every obstacle, and there will be such an impetus given to his exertions as will impart such life and animation to his entire being as to take away all sense of isolation. Isolation! surely no thoughtful man surrounded by the wonders of animated nature can be sensible of such a feeling.

"Another—a drawback to the young student—is low pay, yet by practising strict economy, sufficient funds may be accumulated wherewith the requisite materials for his studies may be purchased. And, then, perhaps the greatest hindrance of all is bothy life. Most young men in places of any extent pass a few years in the bothy, and it is but seldom that three or four persons so thrown together prove to be alike in their dispositions or inclinations. Very rarely is it that all are alike earnest in the pursuit of knowledge or in self-culture; one may be studious, while another may be musical, and it is no easy matter to solve a mathematical problem with an accompaniment on a concertina, or to devote oneself to any pursuit requiring much thought with a set of noisy companions.

"The different studies which a young gardener may profitably pursue are too numerous to mention here; it will, I hope, be more useful if those branches are named a knowledge of which may be considered to be indispensable. These are botany, vegetable physiology, chemistry, mensuration of solids and superficies, geometry, free-hand drawing, the harmony and contrast of colour; and to these may be added the study of entomology, soils, manures, heat, and light. Other subjects equally important will be sure to force themselves upon the mind. A young gardener should be no mere schoolboy taking to his lessons at stated periods, but should endeavour to put the theory of his evening studies to practical application and proof, so far as he consistently may, in his daily occupations.

"As those works which are essentially necessary to the student are most of them expensive they should be chosen with care. Those which partake of the character of an encyclopædia are the most useful. For chemistry, botany, geometry, free-hand drawing, Latin, and geology, nothing can be better than Cassell's new 'Popular Educator;' for scientific gardening generally, Thompson's 'Gardener's Assistant,' and Johnson's 'Science and Practice of Gardening;' 'The Vegetable Kingdom,' by Dr. Hogg, is also a valuable work. These are all illustrated books, which adds very much to their usefulness as aids to the student. For the study of mensuration I know no better work than Nesbit's 'Mensuration.' In addition to books, a microscope and case of drawing instruments are very useful. A good-enough microscope can be had for a guinea, and

a box of excellent drawing instruments for 10*s*. It is advised to purchase good instruments, especially compasses, as it is impossible to work accurately with loose-jointed compasses.

"I have omitted to mention with the other leading subjects for study the geography of plants, an important and highly interesting study, a knowledge of which is calculated to materially assist us in our efforts to afford each plant a temperature and soil similar to those in which it is known to flourish in its native country—to produce, in fact, an artificial climate as nearly similar to the natural one as possible.

"With the wish that these few hints may prove useful, I will bring this paper to a close, only pausing to observe that that man must best succeed in his calling who, in addition to thoroughly mastering its fundamental laws, also makes it his life's study.—Edward Luckhurst, *Egerton House Gardens, Kent.*"

A CHRISTMAS RETROSPECT OF THE FUNGUS SEASON.

[The following *jeu d'esprit*, written by one of our contributors, an enthusiastic fungologist, is so full of wit that we believe our readers will thank us for printing it. Nearly every word is a play on some well-known genus of fungi and equally well-known authority on the subject.]

"December 25th, 7 P.M.—Gentlemen—We have had a grand *Agari-cultural* season this year, particularly in the rich vale of *Berkeley*. Spores have been up, and mycelium active, fungologists have not had *Mush-room* to complain, for fungi have been so abundant that a *Batsch* might have been swept up with a *Broome anywhere:* not, indeed, like certain seasons, when fungi prove so scarce that one might naturally imagine some *Roques* had been and *Hyd'n'um*. We have *Cooked* a good many species this year, and had some very *S(p)hæria Fries* and no *Phallus-y*, not needing the accompaniment of *Currey*, or any other condiment. Not to b-*Link* the question, however (or to be wanting in *Curtis-y*), fungi are not without a certain *O(i)dium*, but no one can deny that edible *Tode-stools* are better than *Bad-ham Cooked* by any *Bunt-ing Hussey*, for you see they never *Pa-nus*, neither are we ever attacked by *Delirium Tremellas* after dining.

"P.S.—9 P.M.—Since writing the above some of my guests have expressed their opinion as to the advisability of sending it to The Journal of Horticulture.

"Guest No. 1 merely says '*O-dont-ia* ! ! !'

"Guest No. 2. 'I don't think Dr. Hogg will like that reference to *Bad-ham*.'

"Guest No. 3. 'Don't let us have any more contents out of that *Crucibulum*.'

"Guest No. 4. '*Dry-rot* it (!), I can't understand it.'

"Guest No. 5. 'Such a fanciful flight is not worthy of true wings (only *Cham-pignons*).'

Guest No. 6. '* * * * *.'—W. G. S."

VIVIPAROUS BRITISH FERNS.

So many interesting instances of the proliferous tendencies of our native Ferns have come under my own immediate notice as to warrant me in placing them on record. With this object it is my intention briefly to refer to a few facts having indirect reference to the present subject, then I propose, *seriatim*, to show that proliferous Ferns are formed on the candex; on the rachis; on arrested, or dwarf, or deformed fronds; on incipient sori; by morphology; and from pseudo-bulbs.

In January, 1854, Newman in his "History of British Ferns," names Polystichum angulare as the only British species that produces bulbillæ. In the spring of that year bulbs were detected on one of my seedling Scolopendriums, when, having communicated my discovery to a leading amateur authority, he examined his own plants, confirming the fact by finding similar formations. By the close of that year, with his further assistance and that of the Curator of the Oxford Botanical Gardens, ten species were found to be viviparous. Subsequently the late Mr. Jackson, of Barnstaple, discovered that the stump of a frond, though several years old, if removed with a bit of the caudex is capable, with the assistance of bottom heat, of forming several bulbs.

I now refer to my own experience.

Having noticed that Scolopendriums occasionally emit roots from the rachis, a frond was selected that had thus formed a single rootlet; it was potted off and placed under a glass shade. At the end of a year the frond had almost decayed away, and a small bulb was growing on the rachis.

Athyrium Filix-fœmina has with me only once been proliferous; at present a small seedling plant of uncum ramosum has several bulbillæ on two dwarf and curiously ramose fronds.

Scolopendrium Wardii is a dwarf and very ramose variety, having a massive multifid head. It is supposed to be a seedling sport of laceratum. It never seeds, though in a warm moist atmosphere it becomes highly proliferous, all its numerous apices being furnished with young Ferns, whilst the surface of its fronds only produce a few. Very rarely one of these young plants assumes a perfectly distinct form—viz., pseudo-Wardii, being very and acutely ramose; this variety never bears bulbs, but is profusely soriferous. A large batch of its seedlings have assumed both forms, pseudo-Wardii being in the proportion of about five to one of Wardii.

Adiantum capillus-Veneris is erroneously regarded as being viviparous, when, in a congenial temperature, its spores vegetate on the sori. A plant of this species (rotundatum), that has not yet fruited, produced a normal frond of two pinnæ; the rachis decayed at the base, throwing the frond on to the surface of the soil. On one pinna three bulbs have formed, and four on the other, exactly where incipient sori may be supposed to be situated.

Plants of Adiantum bulbiferum, that I gathered in the Isle of Man, have on four separate occasions formed fronds, which by morphology have, in place of expanding their pinnæ, become a cluster of bulbs, each pinna forming one.

A depauperated and fertile plant of Asplenium Adiantum-nigrum that I found in North Wales, has at the base of each rachis a pear-like enlargement that remains when the fronds fall off, which latter are apparently attached by a similar contrivance to that exhibited by Woodsia, leaving a cluster of pseudo-bulbs bearing a striking resemblance to the miniature stool of an Orchid. The vitality of these bulbs has not been tested, though it is almost certain that with careful treatment each is capable of forming a plant.—A. Clapham.

KEEPING BLACK HAMBURGH GRAPES.

Having read an article in the number of December 2nd, "How we Got over our Peach Failure," I offer a few remarks as to how I managed to keep Black Hamburgh Grapes in a perfect state up to the present time, having several vineries, and not forcing any of them.

As a matter of course, the Grapes all ripened about the same time, but having been recommended to adopt the method I am going to describe, I immediately made a beginning. Taking a number of empty blacking bottles, I washed them thoroughly clean, filled them with water, adding to each bottle at the same time charcoal broken in pieces the size of a pigeon's egg. On the 15th of September I selected several bunches, some that were scarcely ripe and the wood in a green state, others quite ripe and the wood perfectly firm. I then proceeded to cut the shoot two or three eyes below the bunch, and I put the stems into the bottles in a slanting direction, so that the bunches hung clear from the sides.

The result stands thus:—Of the ripe bunches the stalks withered, those of the unripe did not, the stalks being as perfect as the day they were cut. The berries of none of the bunches have shrivelled, and the flavour is as good as on the day they were cut, if not better. They were put away in a dry attic, where they had plenty of light and a free circulation of air. I may add that as the water evaporated the bottles were refilled. When I now write (December 18th) they look as though they would keep good for a couple more months.

I make these remarks for the use of those who may not have an ice house, and during the last two winters no ice could be obtained in this part of the country.—J. S., *Eccles Hall.*

FRENCH POPPIES.

I was much struck last May with the beauty of a bed of French Poppies, which, sown the previous summer directly the seed was ripe, had grown bushy and strong, and rewarded amply their owner, who, with much trouble, has collected about thirty varieties, all varying from 1 to 2 feet, and running through every shade of crimson, scarlet, orange, rose, pink, blush, lilac, cream, white—bordered, striped, spotted, fringed, flounced, and self—and varying from large single blooms to

hundred-petaled ones, vying with the Rose for beauty, the fragrance, alas! wanting. I have often wondered that these gems were not more cultivated, and a succession of sowings would carry on the bloom till late in the autumn. Sunshine they must have, and they blossom best on a rather poor soil. —Devon.

[We omitted the last sentence in your note. From experience we can testify the persecution it occasions to the generous.—Eds.]

MOISTURE IN THE AIR OF A VINERY. HYGROMETERS.

1st, What amount of atmospheric moisture is proper to be kept in a vinery in the different stages of growth? Also what is the best way of constructing a hygrometer, or for what price and where can a moderately good one be purchased? The Vines are started on the 1st of February.

2ndly, Last year my Vines were started on the 23rd of January. In March and April, when in leaf, we had several fierce sunny days, but with a sharp, cutting, easterly wind, and in giving air to keep down the temperature the leaves suffered severely, the greater part of them turning quite yellow. I shall be glad to know what is the best management for a vinery under such circumstances as the above, both as to giving air and moisture, so that the leaves may be kept healthy.—T. H. D.

[The subject is a very large one and to go into it fully would require more details than could be entered upon in a short answer, or even an article. We cannot give you the prices of hygrometers, as they vary according to the kind, the workmanship, and the nicety of observation required, and instructions generally accompany the instruments. Of these, Daniell's we still consider the best. There are many simple hygrometers which sufficiently tell roughly the vapour existing in the atmosphere, such as pieces of wood, and long hairs deprived of their oily matter by washing in hot water containing a little dissolved soda; any textile fabric, as flax, will always tell in a rough way, and so will any kind of cord, catgut, seaweed, &c. We know many farmers who keep a piece of seaweed in their sitting-room, and depend as much on that as the best of barometers. When there is much vapour it becomes soft and clammy to the touch; when the air is dry the seaweed is also dry. All the cords and textile fabrics alluded to above contract in a damp atmosphere and lengthen in a dry one. We once had a very useful simple hygrometer. It consisted of a piece of catgut 6 feet long; one end of this was fixed by a pin to the wall, and the catgut was taken horizontally about half its length, and then turned over a wooden peg with a groove in it, the loose end hanging down perpendicularly, with a small piece of lead attached to it to keep it so, and in that lead a peg or pin of 2 inches long, or so, was fixed, so as to pass up and down in front of a slip of wood some 18 inches long, with lines made across with a pen at regular distances. The pin or index rose or fell, just as the catgut contracted or lengthened.

Next to Daniell's hygrometer for correctness, and, perhaps, the simplest as formed on the same principle, is merely to have two thermometers suspended close to each other, and which are seen to denote, when left alone, the same degree of temperature. Place one wrap of white muslin or silk round the bulb of each thermometer. Leave then the bulb of one thermometer dry to denote the temperature of the atmosphere. Keep the bulb of the other thermometer, with its covering, wet, by a phial or other vessel of pure water suspended over it, and a thread of floss silk or fine wool passing from the vessel to the bulb. The difference in temperature between the dry and the wet bulb enables us to measure the amount of vapour in the air of the house. Thus, supposing both bulbs were within from 1° to 6° of the same temperature, we should consider that the humidity was quite ample. Should even the wet bulb fall to as much as 7° to 10° below the dry one, there would not be much cause for alarm in general; but when the difference reached 12° or 15°, or more, then the extra dryness would become dangerous, and especially in cold frosty nights.

Now, to apply the above, so as to give an answer to your second inquiry, in all glass houses the greater the difference between the external and the internal air, the greater the necessity of attending to atmospheric moisture. Hence, on this account alone, a comparatively low safe temperature at night is not only safest and healthiest for most of the plants we grow in forcing heat, but it involves least trouble as respects the necessary atmospheric moisture. Much less attention will also be required in houses whose glass roofs are close, without laps, and also somewhat in proportion to the thickness of the glass, as, other things being equal, the thicker the glass the more heat will it keep in, and therefore in a cold night there will be less condensation of moisture on its inner surface, that condensation always tending to make the air drier. The greater, therefore, the difference between the internal and the external temperature, the greater will be the condensation, and that much more than in an arithmetical ratio. This condensation is one of the causes of the air in houses becoming too dry. It has been computed that each square foot of glass of ordinary thickness will cool 1¼ foot of internal air as many degrees per minute as the temperature of the inner air exceeds that of the outer air. Thus, if the outside air should be 30°, and the inside 60°, the vapour in the 30° difference would be precipitated or condensed against the glass or bars, and either run out of the house or hang or drop in it. The capacity of air for moisture is greater the higher the temperature, and that much more than in a regular gradation. Thus, air at 66° will hold a double amount of invisible vapour as compared to what it would do at 44°; but it will hold three times as much at 80°, and four times as much at 90°, and so on. Air escaping at 80° takes out with it four times as much vapour as would come in with air at 44°. An idea may therefore be formed of the parching effects of letting air out of a house, say at 65°, and admitting frosty air at 20°. A second chief cause, therefore, why the air of a high-temperatured house becomes overdry, is the free escape of the heated moist air against our will through lape in the glass and other crannies, and our voluntary admission of the cold air by ventilation. A third mode of overdrying the air may be here referred to, and that is when such porous materials as soft flues were used in houses with a high temperature. Close hot-water iron pipes give just as dry a heat as the flue would do, but then the pipe from its hardness cannot greedily, like a soft flue, suck in the moist vapour.

Now for a practical application. We believe that much injury in old times was the result of having an atmosphere too hot and too dry; and in modern times, though an atmosphere saturated with vapour would tell most favourably on all annual and succulent growth, and is most needed there, this extra humidity, if maintained, would tell injuriously on the flavour of fruit and the ripening of the wood. For deciduous plants, such as the Vine, it is most needed when the shoots are young and soft, and when the fruit is also small; but as the latter becomes well swelled, the air of the house should become gradually drier. We may take a lesson from what disappoints us as well as from that which succeeds. Many a Peach tree on the open wall fails, if not in fruit, at least for a time in healthy shoots, because when these shoots are young and soft the air is too dry and parching for them. We can neutralise the dryness in the houses, and here the simplest modes are generally the most effectual. In the general run of plant houses, where the forcing heat seldom goes beyond 45° or 50°, little or no trouble need be taken about atmospheric vapour if ventilation be given in moderation, and the external temperature should not be very low; but in severe frost, when more firing is needed, it may be necessary to damp the stages and the pathways, and even the floor, with a syringe. Giving air sparingly, at the top of the house will be much better than larger fires and accompanying evaporating pans. The vapour rising from the pots and the floor will, except under these circumstances of extra cold, be quite sufficient.

Then, again, in the case of Vines, little additional vapour would be needed for the first three weeks of forcing, but as the buds break and lengthen more will be required—that is, as the heat of the house rises to 60° and onwards. Generally, evaporating pans on the top of flues and pipes will be the best for this purpose; but on extra occasions, such as a bright sun in sharp frost, the floors and pathways should be sprinkled in addition, but in such cases less depends on additional atmospheric moisture than in preventing it unduly escaping by free ventilation, and this should be regulated by preventing fire heat and sun heat acting on the enclosed atmosphere of a house at one and the same time. The beams of the sun will tell quite as well if there be no great openings in such cases for the entrance of cold, dry air. In dull, mild weather out of doors, less artificial vapour will be wanted than when the external air is cold and frosty.

It is just possible that in a vinery started on January 23rd the leaves suffering severely in April, so as to turn yellow during a few days' fierce sun and cutting east winds, might be

partly owing to the Vines growing in a high temperature previously, and in dull weather, and in an atmosphere saturated with moisture, the leaves thus becoming thin, and less able to bear a sudden change and the full force of the sun's beams. But allowing the result might be partly owing to this, we are inclined to think it was chiefly owing to giving too much of the cutting east wind to keep down the temperature, and more especially if there was the meeting of a strong heat from the heating apparatus with the more natural heat from the sun. No rule in such a case will be equal to an observant eye. Whenever under such circumstances there is a likelihood of a bright sun, the apparatus for heating should be allowed to become cooled, and then the sun may shine freely, with only a little ventilation at the highest part of the house, and the air admitted is thus warmed and moistened before reaching the plants. It is well to have cold, dry, fresh air heated and moistened before admission, but that is as yet comparatively seldom done; and the next best plan is to give air early under such circumstances as those referred to, and very little will do if the sun heat and fire heat do not meet, for a rise of 10° or 15° from sun heat with air on, is a very different affair from a rise of half that amount of heat from fire heat alone.

With regard to details as to temperature, supposing you begin, as respects a vinery, at 45°, raise it gradually to 60°, but never above with artificial heat until all the buds have broken and commenced growing, when the average night temperature might rise to 65°. For a short time, when the Vines are in bloom, the heat may rise to 70° or nearly so; and when all set the night temperature may range to an average of 65° for all the hardier Vines; Muscats may have a little more. Now, during the day, even in dull weather, the house averaging from 60° to 65° at night may rise at midday to 70° or a little more; but as the Vines advance, and if the fires were low, and a little air early given, and thus the heat rose very gradually, we would sooner let it mount to 80°, 85°, and 90°, and even higher, from sun heat, before we would lower it by admitting at once a great quantity of cold, dry, frosty air. We have thought over the matter quietly before penning these ill-connected remarks, as we would like to be useful if we can, but all utility is best accomplished by united action, and you will much help if you would kindly state if our surmises as to your case are at all correct.

In conclusion, we may mention two similar facts that came under our own observation. A house of beautiful Cucumbers was heated, as one of a number of houses, from one boiler. In a bright sunny day in the beginning of April, with a cold, piercing east wind, hardly any air had been given, the valve of the water pipes had not been touched, and on opening the door the temperature from hot water and hot sun was enough to make one go out, as it was past one o'clock. Without giving time for thought, top and front ventilators were thrown open to a considerable extent, and in, of course, rushed the dry, parched air, and in ten minutes the house was considerably cooled, but fully two-thirds of the foliage—all the fine, large leaves, were scorched and shrivelled up as if a blast from a furnace had passed over them.

In a similar case, about midday, the head gardener having just returned from a journey, saw at once the plants were distressed, put his head in at the door, felt, and pretty well burned his hand on feeling the pipes, turned the valve to stop the circulation, sent one lad to flood the floors and passages with water, sprinkled the beds and under sides of the leaves with water at 80°, and, having no shading handy, syringed the outsides of the roof with whitened water, and just increased the air by a little at the top. By evening the plants were all right, showing no trace of the ordeal they had passed through. The circumstances, as respects hot-water heat, and sun heat, and cold, dry external air, were so much alike that we have not a doubt that the results would have been identical in the two cases if a similar practice had been adopted. In either case, if, as the sun began to gain power, the hot-water pipes were gradually cooling, and a small portion of air had been given early at the apex of the roof, the temperature gradually rising from sun heat would have been beneficial rather than injurious, and with damped paths and evaporating basins under such circumstances we would rather have let the thermometer rise to 90°, or higher, before we would have freely admitted a cold, dry, frosty air. In early forcing, the leaves of some Vines will be apt to suffer, when, after a week or a fortnight of dull misty weather, we are favoured with even one day of bright sun. A slight shading for a little will generally obviate all inconvenience. As already stated, however, the chief securities from such injured foliage are a comparatively lower temperature at night than by day, proportioning the vapour in the enclosed atmosphere to the artificial temperature, preventing fire heat and sun heat from acting much together, and in bright sunny weather, with a keen, cold atmosphere without, giving a little air early as soon as the sun begins to raise the thermometer in the house, and then, in preference to giving much more air, allowing the sun to raise the temperature from 10° to 20° gradually above the night average, and letting it fall as gradually. —R. F.]

PIPE FLUES.

The able writer of "Doings of the Last Week" has asked for information respecting small pipe flues, or rather the smallest size which can be used for the purpose, and subsequently another inquiry from Yorkshire on the same subject has re-opened the question. As the latter has reference to building, or rather heating a forcing pit 40 feet long, no apology is wanted to enter still further into the subject of flue-heating. In reply to "R. F.," I may say that I have known a short length of 6-inch pipe used advantageously for some years as a flue, but it was an iron pipe, and the trouble of cleaning it often was such as to cause much regret that it was not larger; but, like many things of the kind, it was put in as a makeshift, and remained for many years, occasioning much grumbling every time it had to be cleaned. There may, however, be places where a flue of such small diameter may answer better than the above, and these are where only coke and wood are burned. Coals create so much soot that a flue soon becomes choked up, so that I would certainly not recommend a small one; and even for a pit where the volume of air to be heated is small, and the space the flue occupies is otherwise valuable, I would certainly not recommend that any flue pipe should be less than 9 inches in diameter inside, and more if the house to be heated is of greater cubic content. Where coals are cheap, as I imagine they are where "C. A. B." resides, a flue of this description will, I am persuaded, be a formidable rival to the much-vaunted hot-water apparatus.

As I have before stated, I would advise that only the straight portion of the flue should be of pipes, and the turnings and entrance of brickwork, with some suitable cover that could be taken off, so as to allow the pipes to be cleaned out when necessary. In small pipes or flues it is a good plan to have a copper wire in the flue, in order that a string and some sweeping material may be attached to the wire for cleaning out. In a larger pipe this is not so necessary. A bunch of Holly, followed by one of straw, is not an unusual sweeping brush; and it very often happens that the position of such flues prevents long-handled tools being applied, so that the wire left in the flue is of great service at cleaning-out time.

I have before said that it is better not to disturb the joints of cement pipes, and that brickwork, with covers, forms the corners and end pieces to the flues of the two houses I have so heated; but for "R. F.'s" information I may add that the flue to each house dips about a foot at the doorway, without appearing to suffer much in consequence, the dip being gradual and easy. The two houses, however, being together, the fireplaces are in the usual way just behind the partition, and the flues starting low cross the pathway at the partition door with their tops on a level with the pavement, and, rising easily and turning to the front, unite with the pipes, and proceed along the front, where a corresponding dip to meet the end door is made. Then, after a similar turn and rise, the front flue enters the back pipe flue, which proceeds to where it started from, and then into an upright chimney. There being only one dip at the end door, and that of about a foot, we have never felt inconvenience from it in any way. True, like all flues, there is an unpleasant smell when a fire is first lighted after the flue has been out of use for a long time; but so far as I could judge, the smell arose more from the brickwork than the cement pipes, and when once warmed it all goes off. In districts, therefore, where coal is plentiful and cheap, I am of opinion that the flue is still a powerful opponent to hot water, and especially in small structures or solitary ones. To your correspondent "C. A. B." I would therefore say, Inquire in your neighbourhood where good Portland cement pipes of not less than 9 or 10 inches in diameter are to be had, obtain one, and try it over an Arnott stove, or something of that kind, that will subject it to as great a heat as it is likely ever to encounter, and if satisfactory, erect a flue accordingly, or perhaps a smaller pipe as a trial one would be better, as it would be heated more.

The fixing of cement pipes is a very simple affair, as they are prepared with socket joints; a small quantity of cement only is required to unite them, and a rag tied to the end of a stick to smooth away any of the cement that squeezes through ought not to be forgotten, otherwise the cement would harden into an ugly protuberance. If the corner or end cover of the brick flue be laid aslant, so that it may be easily taken off to clean the whole out, so much the better. As I expect "C. A. B." will place the flue in the front of his forcing pit, he might so arrange the end pieces as to take off easily, and a wire left in the flue will be very handy.

If coke or other fuel producing little smoke be used, the pipes might be smaller, but in coal-producing countries the raw material is often the most abundant, and it is not always that those managing the fires can be persuaded to economise coal, so as to give a chance of much of the smoke being consumed before it reaches the flue. It would, therefore, be better to allow for this by having the flue large enough.—J. Robson.

CONSTRUCTION OF A FLUE.

I have read with much interest the remarks in your columns relative to heating by flues. I have had some little experience in the above matter, and perhaps you will allow me to communicate my ideas thereon.

One old-fashioned mode of constructing a flue is three courses of plain tiles, or a single course of foot tiles for the bottom, three courses of brick-on-edge for the sides, and foot tiles for the top, the interior well plastered with a mixture of cow dung and lime. The lime might perhaps be dispensed with, but in my opinion it tends greatly to make the flue smoke-tight. A correspondent in the Journal of December 16th complains of the plastering falling down through explosions. I have never found this occur, and fancy his flue must be too small, and also badly constructed, for explosive gas to collect; probably he burns coal. A golden rule in the construction of a flue is to sink the furnace low enough. No portion of the flue should be lower than the firebars. This is especially important where it is necessary for the flue to descend to clear a doorway. The furnace should be within the house, of 9-inch brickwork, and the top of fire tiles set with fire clay. It should not be too large, or the fire will fall back and will not burn so steadily as when kept in a compact mass. A furnace a foot from front to back, inside measurement, is large enough for a greenhouse 16 feet long. At the same time it can easily be reduced in size by piling up bricks at the back. Close-fitting furnace and ashpit doors are essential, the latter provided with a ventilator. Any ordinary bricklayer can easily manage the construction. I have entrusted the management of such a flue to ordinary labourers and female servants, and have always as yet contrived to preserve my plants.

My instructions for lighting are, when the fire burns clear, to add fresh fuel and shut the ventilator, which is prevented from entirely closing by a small pin. The great risk is in overheating. If the ashpit door should be left open, the furnace, furnace door, and part of the flue would probably become red hot, and the plants sustain damage. It is in this point that the hot-water system is so much superior to the flue. Many amateurs fancy that if the fire go out during a frost they are running a risk, but they need not be alarmed on this score. In a frost of perhaps a week's duration, with dull sunless days, and perhaps 5° or 6° of frost during the daytime, I have found I could always maintain a temperature of 40° during the day, though the previous night's fire has burnt out hours before daylight. Coke is the best fuel.

In conclusion, I would recommend amateurs about constructing a greenhouse to heat it by the flue, on the score of economy, and if possible to place the furnace so that it can be attended to without going out of doors; then the trouble of management will be reduced to a minimum.—Fair Play.

THE CLARKSVILLE GRAPE.

Enclosed I send you an aërial root from a Vine of the "Scuppernong Grape," growing in our yard. There are hundreds of them hanging down from the large limbs, from 1 foot to 3 feet in length, like a huge fringe. They make an annual growth of about 1 foot, most of which is killed back the succeeding winter, so that they rarely reach the ground. Whenever they come in contact with the earth they burrow in it like a mole, and throw out numerous lateral fibrous roots very rapidly. You will notice the ends of these roots are armed with a hard spur, for the purpose of forcing their way through the earth. So you will see the habit of this Vine is similar to that of the Banyan, or Indian Fig. By training the Vine so as to let these aërial roots take hold of the earth, I have no doubt a single Vine might be made to cover an acre or more of ground. The main roots put out by seedlings of the Scuppernong the first year, are in like manner furnished with this spur-like appendage, from the sides of which fibrous lateral roots grow. The Vines of this species of Grape have just finished blooming; the berries are now from the size of squirrel shot to that of large buck shot. They grow very vigorously, and will be nearly or quite grown in a month, and ripen in October.

The crop this year (1868) is very promising, and will be large if not injured by storms. This Grape is never attacked by insects or diseases in either Vine, leaf, or fruit, so that a crop is very certain.—Country Gentleman.

[The Scuppernong Grape, according to Downing, is "Vitis vulpina, Lindley; Vitis rotundifolia, Michaux, a southern species growing wild from Virginia to Florida, and climbing to the tops of the tallest trees. The species is diœcious, and too tender for a northern climate."]

GLAMIS CASTLE, FORFARSHIRE.

The Seat of the Earl of Strathmore.

(*Concluded from page* 479.)

Peaches occupy the second place of importance at Glamis, three houses situated at the ends of the long vinery range being devoted to their culture. The trees are planted in the usual manner, and trained on trellises in front, and also against the back wall, a dwarf and a rider, or 6-feet standard, alternately; the intention having been to cut away the riders, and let the dwarfs form the permanent trees. The riders, however, having at first the best position, have succeeded so well—better than the dwarf trees—that Mr. Johnston intends to preserve them, and we think he is right. We have frequently observed that Peach trees in the form of riders become the most fruitful, especially when young, as in this case. The crops in all the houses, Mr. Johnston said, had been good; at the time of our visit the fruit was entirely over. The trees were pictures of health, perhaps a little too vigorous in some instances, a tendency Mr. Johnston was attempting to check by allowing the red spider to have its fill—a questionable practice, some will say, for repressing excessive vigour, and at first sight it may seem so, no quarter to the red spider being the common watchword; yet we have ourselves at times employed the same evil agent, and been benefited.

Pine Apples are not so largely cultivated as might have been expected. The young and succession plants are grown in some narrow low brick pits, which we were rather sorry to see occupying the position they do in front of the principal plant houses. These old-fashioned structures ought to be banished from all good modern gardens, for they are only fit for growing some rough bedding plants or common Cucumbers. In the long range of three-quarter span-roofed houses, the fourth from the end, measuring 40 feet long by 16 wide, and of considerable elevation, contains the fruiting Pines, which are plunged in fermenting material in the front half of the house, there being a walk down the centre. Here Mr. Johnston had some splendid examples of Queens, which when fully ripe would average 5 lbs., and the whole stock was exceedingly healthy and sturdy, altogether in fine condition. The back part of this Pine stove is devoted to the culture of Bananas (Musa Cavendishii), planted out, having plenty of heat supplied to their roots, which, and a copious supply of moisture, seem to be the principal requirements of these fruits. The temperature, &c., of the Pine stove seem to suit the plants admirably, for here they were producing some magnificent clusters.

Another house in this range, of about the same dimensions as the last, is devoted to Figs, the trees being planted out in the borders, and grown like so many Gooseberry bushes. This idea is very good, yet we fear the result will not be so gratifying. Figs when planted out thus become so extremely rampant, that it is scarcely possible to keep them within bounds, or to make them fruitful. Here, although the plants were still young, and but lately turned out of pots, the shoots were far too gross for fruit-bearing. To fruit Figs successfully, they must either be grown in pots, or, if planted out, allowed plenty of scope, and then when aged they will bear profusely. Brown

Turkey, or Lee's Perpetual, White Ischia, and White Marseillea *alias* White Genoa, seemed to be the most productive; and Castle Kennedy, Mr. Johnston stated, bore a close resemblance to Brunswick, although larger, and positively refusing to bear in a young state.

Melons are grown to great perfection by Mr. Johnston, and occupy some of the three-quarter span-roofed houses of this range, which are particularly well adapted for the purpose. A length of about 80 feet, divided into four compartments of 20 feet each, was filled last season, three compartments with Melons, and one with Cucumbers. These houses, or pits as they might be called, are about 8 or 10 feet in height, and 10 feet in breadth, having a pathway in the centre, and in front a bed about 3 feet wide, heated by hot-water pipes below; in this the Melons, &c., are planted. They are trained to a trellis overhead, and thus magnificent crops are produced. Melons and Cucumbers have a charming appearance when grown in this way. The soil in which they are grown is the same as that used for the Vines, and it seemed to answer exceedingly well, for more healthy and vigorous Melon plants we scarcely ever remember to have seen. With regard to the soil, Mr. Johnston said it appeared to suit almost every plant, everything growing with much vigour in it, and certainly his productions did not belie the character he bestows upon it.

We now come to plants and flowers, which do not occupy nearly such a prominent position in these gardens as fruits; but they are sufficiently numerous, and, in general, so well cultivated as to form an important feature. The first two houses in the centre of the magnificent vinery range, one on each side of the middle entrance gateway, are stoves 40 feet long, 22 feet wide, and 18 feet high. In the centre of the houses is a flat slate stage, with a walk all round, and narrow stages in front. These houses are principally occupied by ornamental-foliaged plants, very good examples being present of various Palms, which we are glad to see coming so much into cultivation, Ferns, Coleuses, &c. A prettily-fruited plant of Podocarpus purpureus, with its charming light violet berries, was very striking. Planted-out and trained to the back wall were some remarkably large and fine plants of Allamandas, which when in flower must be glorious. Euphorbia jacquiniæflora grown in the same manner, had made shoots upwards of 10 feet in length, fully 4 feet of which seemed to be set with flower-buds. This is a chaste and charming flower at all times, and as the smallest portion is always pleasing, what must be these plants of Mr. Johnston's when they are in full flower? Four feet of a floral garland of this gem! Fancy a plant 10 feet in height, and as much in diameter, leafy to the ground, and full of flowers. Bougainvillea lateritia and spectabilis were also doing well, and on the roof various climbers were growing vigorously, the flowers of Passiflora kermesina enlivening the scene with their pleasant tints. Shading is provided for these houses by hanging up in the interior, close to the roof, broad pieces of thin tiffany. This when fixed in a graceful sort of festoon is very pretty, and prevents the disfigurement of the houses outside by covering them up, as is generally done, with tattered shading.

In the other range of houses, the centre three-quarter-span is called the show house, a sort of conservatory of greenhouse flowering plants, 40 feet by 22 feet in width. Here were a very fair assortment of Pelargoniums, &c., and some plants in full flower of that pretty gem Statice profusa, which is always to be seen in such abundance at Dalkeith. To the right of the show house is the Camellia house, of the same dimensions; in this the Camellias are planted-out in beds, which in a few years will prove very beautiful. Three smaller houses at the extreme end of this range, corresponding to the Melon and Cucumber pits at the other, are devoted, one to the propagation of bedding plants, another to collections of small stove plants, and the other to Heaths, &c.

We would just notice, in conclusion, that the whole of the hothouses at Glamis are heated by one boiler—a tubular saddle, manufactured by Messrs. G. H. & G. Nicoll, of Dundee. It is composed of twelve 5-inch tubes, and its length is 10 feet. The extent of piping attached, Mr. Johnston informed us, was about 12,000 feet, and the whole or any part of this enormous extent can be heated with the greatest ease. How many hatsful of coals may be required to effect this our informant told us not. Here is a boiler, however, about which little fuss is made, with the powers of a giant, and we would recommend it to the attention of our "bigwigs" in that line. We would recommend them to take a look at this before introducing any more of their multitudinous fancy forms, which serve both to perplex and to mislead the public.

We recommend our readers to visit Glamis, and see its noble Grapes; they will there meet with a kindly welcome from its talented gardener, Mr. Johnston, who is a credit to his profession. We thank him for our own kind reception. We only hope we have done justice to our self-imposed task—a task begun on a day of fog and rain, raining as it can only do (sometimes) in Scotland—a "day of real Scotch mist."

WAYSIDE JOTTINGS.—No. 3.

Early in the summer of the present year I decided upon devoting a holiday to the examination of Tallentire Hill, an elevation which, under different names, stretching from east to west, separates the valley of the River Ellen from that of the Derwent. For this purpose I left the early morning train from Carlisle to Maryport, at Dearham Bridge station, about two and a half miles eastward of the latter town. I sauntered along the banks of the Ellen for some distance without discovering much to interest me in a botanical point of view, except, perhaps, the pretty heads of Anthyllis Vulneraria, or Lady's Finger, which seemed to spring up spontaneously upon the loose banks of the disintegrated and mouldering rock which forms the slopes of the railway cuttings and embankments of the line over which I had travelled, and which runs parallel to the river for some miles towards the Maryport end. On the southern bank of the river, where the slopes are pretty abrupt, and where, in consequence of the steepness, large patches of similar débris appeared quite destitute of vegetable covering, the idea suggested itself to me that, supposing this plant possessed any value as a grazing or forage herb, it might be utilised by cultivation in such situations.

On reaching Crosby Mill I crossed the river, but before quitting its banks I stopped to admire the rugged and broken manner in which the carboniferous strata of rocks appear denuded at various points of my morning's walk along the valley. Had great upheavings of the earth's upper crust not taken place, much of the mineral treasure of coal, lime, building stone, &c., which now constitute the wealth of the neighbourhood, must have remained hidden at unattainable depths. Pursuing my walk I next ascended a ravine down the bottom of which a small brook, almost dried up at the time of my visit, flowed in the direction of the river. The slopes were covered with underwood, principally composed of Hazel intermingled with the wild Dog Rose, several varieties of which were in full bloosom. Under the shade of this brushwood I found the Sanicula europæa, Wood Sanicle, growing in profusion. A few stems of Serratula tinctoria, Saw-wort, were also springing up at intervals, though the flowers were not yet developed. At the top of the ravine, on its western side, was a patch of springy turf, the glossy green of which was relieved by spikes of the bright yellow flowers of Genista anglica, Petty Whin. Along the edge of a footpath, too, I noted an abundant growth of Plantago maritima; but its flower spikes had not made their appearance.

A little way higher up I found myself upon the high road, which I followed up to the village of Tallentire, on entering which I saw some old hedgebanks of rude stonework apparently raised by bygone generations, covered with the pretty little flowers of Geranium lucidum, Shining Cranesbill. The leaves and stems, as well as the flowers, showed a glowing crimson tinge, which contrasted well with the framework of grey lichen-covered stones, that pushed their venerable heads at intervals through the surface of the bank; all the more graceful that no workman's hammer or chisel had sought to rob them of Nature's own polish. Turning sharply to the left, and ascending a steep incline, I found myself at the white stone quarries from which much building stone is procured. The strata of rock appear much distorted, and the working of the quarry must be a task of considerable difficulty. A little way above the quarry, on the sloping bank, studded with Cowslips innumerable, I found a few fronds of Botrychium Lunaria, or Moonwort, a species of Fern occasionally met with in elevated pasture ground like that on which I was just entering, and where the soil is seldom very fertile or the herbage luxuriant. A little to the southward of the summit level I stumbled upon a bed of the pretty dwarf Dark-winged Orchis (O. natulata), just peeping above the scanty herbage of the "Tarnities," as the extensive pasture is called. Some of the clusters of imperfectly developed flowers appeared at first sight more like little maroon-coloured fungi than Orchids, such as a nearer examination proved them to be.

Following the summit level along the ridge, I greatly enjoyed the fine prospect on both sides which my elevated position com-

manded. Among the crevices of the loose rock, which cropped up here and there like the ruins of some long line of ramparts, I gathered specimens of a plant which I had not previously noticed in my rambles. This I discovered to be Poterium Sanguisorba, or Salad Burnet, a plant which I have since found growing plentifully among the crevices of the limestone rock, particularly in places where the rock had been long since excavated for conversion into lime.—H.

GARDENS AND GARDENING AROUND HAMBURG.

Whilst on our visit to the Great International Horticultural Exhibition at Hamburg in September last, which was fully reported on in our columns at the time, we took the opportunity to look around to spy the richness, not the nakedness, of the land —to visit some of the principal seats and gardens of the nobility and merchant princes of Hamburg. At the time of such a great and exhaustive exhibition as this was, embracing as it did nearly every plant and article connected with gardening, and supported, as it was, in the most liberal spirit by all horticulturists in the immediate neighbourhood, the time of our visit was so far inopportune—the main treasures of the establishments for the time being were gracing the great Show, so that much in the way of cultivation which we might otherwise have noted has on this account to be passed over.

Visitors to Hamburg by steamer are most favourably impressed with the exceeding beauty of the country surrounding. Entering on the waters of the magnificent Elbe (a river somewhat in the character of our own Humber), about seventy miles from the mouth of which Hamburg is situated, we have on the right hand, on the south, the province of Hanover—low, flat, and uninteresting, as seen from the river, with an enormous extent of forests in the distance. To the left hand, on the north, lie the Duchies of Schleswig and Holstein, which have of late years obtained not a little notoriety through the war which took place between Denmark and Prussia for the right to impose taxes upon and draw soldiers from them. These were a few years ago a portion of Denmark; now, like Hanover, they are Prussian territory. For some distance the country is flat and uninviting, but within about twenty miles of Hamburg the ground rises considerably immediately along the bank of the river, and the most lovely scenery commences, reminding one not a little of the Thames at Richmond, or rather Richmond Hill from the Thames. Here is the West End of Hamburg; here live the aristocratic portion of the great merchant city, like our own "upper ten," away from the din and bustle of money-making; and we feel bound to admit that for situation, for beauty, for shelter, and for extent of landscape, there are few such places to be met with as this delightful river's bank. Here we spy, as we speed along, a pretty little villa or two, half hidden by the fresh green trees, or maybe the Roses, Clematises, &c., which are covering its walls, and the glorious beds of Pelargoniums, &c., in front, with the grassy bank sloping down amongst the trees and shrubs to the terrace by the river's bank; there a stately mansion with its towers and steeples, its more broad and spacious lawns and terraces, its beautiful gardens and long ranges of hothouses, all, all exposed to our view. From Blankenase, the first place we touch, the most thickly populated, and perhaps the most beautiful, to Hamburg, is one long succession of these pretty villas and gardens, to visit which we must proceed from Hamburg by the high road through Altona, the town part of Holstein adjoining Hamburg, forming to the stranger part and parcel of one city, although under different government, Hamburg being as yet one of the free or Hanse towns of Germany.

NEUMÜHLEN—ALTONA,

THE RESIDENCE OF FRAU SENATORIN DONNER.

This is an extensive and most pleasantly situated place near to Altona, on the banks of the river Elbe, the grounds in some places sloping nearly at right angles more than 100 feet, and clothed with fine old trees, Oak, Beech, Elm, &c., of great altitude, and with fine clean stems for 70 or 80 feet high. These fine trees show the quality of the soil, and give a rich appearance to the place. Herr Reimers, the very intelligent obergartner (head gardener) here, speaks English very fluently, having resided some time in this country, so that Englishmen meet here with the greatest courtesy, as, indeed, is the case everywhere.

The sloping nature of the ground gives a very diversified style throughout the place, portions of the gardens being on one level and some on the other—a sort of terraced style. On one side of the mansion we have low shady dingles or dells, the tall trees overhanging, and pretty little streams of water twisting naturally along amongst the rocks, and Ferns, and Pampas Grass, and Conifers, &c., the whole being extremely pleasing. The house itself stands a little higher, overlooking the river, with its troops of pleasure boats, and huge merchant steamers, passing continuously. A small terraced slope immediately fronts the house, and it was tastefully planted with the usual bedding plants, amongst which Iresine Herbstii looked exceedingly well, and Snowflake proved the best variegated Pelargonium. Around some of the beds was a sort of festooned chain about 2 feet in height, neatly covered with a very pretty little-leaved Cucurbit named Pilogyne suavis. This is a style of ornamenting flower beds peculiar to the Continent, which we have seldom seen adopted in this country. Here a score or two of fine, green, leafy, dwarf, bushy plants, quite covered with bloom, of that much-neglected but exceedingly beautiful plant, Torenia asiatica, attracted our attention; many have given up the cultivation of this plant, owing to its tendency to red spider and mealy bug, cultivated, as it has always been, as a stove or warm greenhouse plant. Here in Mr. Reimers', and in many other gardens round Hamburg, it is cultivated with the greatest ease in pots plunged out of doors during the summer months, much in the same way as we do Salvias, and in autumn, when the flowers begin to open, removed to the greenhouse, where it flowers to perfection, and nothing can exceed the lovely appearance of its pretty blue flowers.

Another plant cultivated here in quantity for decorative purposes, and almost unknown in this country, is Hæmanthus puniceus. Its singular-looking umbelliferous scarlet flowers have a fine effect. It has been found, where tried, somewhat difficult to flower. Mr. Reimers succeeds by keeping the plants rather pot-bound, and in the cold for a time; then, to induce flowering, they are placed in a temperate house. Great quantities of small flowering plants are cultivated here for house decoration in convenient houses for the purpose. Camellias were especially fine, likewise Epiphyllums by the hundred, double Primulas, Begonias, and Salvias, of which S. Suchettii was considered a very great improvement on S. splendens.

Mr. Reimers has also the advantage of a fine orchard house for the cultivation of Peaches in pots, and most abundant were these fruits here last season. The only fault that could be found, itself a serious one, was the too heavy crop on the trees. The trees, which were of the common bush kind, in 15 and 18-inch pots, had some of them three and four dozen fruits of very fair size; we are afraid, however, that the quality would not be equally good. Quantity with quality can never be had with fruits.

We cannot notice all the interesting features of this place. We dare not, however, pass by a small but exceedingly valuable collection of sculpture in a building near the conservatory, executed by the great Danish sculptor, Thorwalsden, that of the Three Graces, in solid white marble, being considered the finest ever executed, and of a most fabulous price. Sculpture being a sister art of gardening, we recommend all fond of the beauty of form, who may have the opportunity, to view Thorwalsden's Three Graces, the most perfect model of the most beautiful form in creation.

(To be continued.)

RENDLE'S PATENT GROUND VINERIES AND PLANT PROTECTORS.

My attention has just been called to an article in your paper of the 16th inst., signed by Mr. Edward Luckhurst. In it he recommends that ground vineries should be constructed of wood and glass, because wood is cheaper than earthenware. He says that his carpenter can produce deal boards 1½ inch thick, 12 inches high at the back, and 8 inches high in the front, at 1s. 4d. per running foot. I do not know how he intends to fix the glass to these boards, but he will find a great difficulty, unless he infringe my patent rights. This idea is not a new one, because I well considered the subject in all its bearings, and my first models were made of wood, and exhibited by me at the Royal Horticultural Show, at Leicester, in the year 1868. But wood will not answer. In the first place the top groove must be at least 1½ inch deep, so that each pane of glass can be "shunted up" into it so as to free it from the under groove. His deal boards, therefore, must be at least 3 inches thick, and this will double the cost. In the next place, how does he contrive to fix his deal boards in the ground? They will not stand by themselves. He must

have four iron bolts with screws to bind them together, and these would cost about 3*s.* to every 3-feet length on the lowest calculation.

Your correspondent has evidently not seen my latest tariff, in which I offer to supply the ground vinery precisely similar to that used last summer by Mr. Rivers, of Sawbridgeworth, with 21-oz. glass, 24 inches wide, at 1*s.* 7*d.* per foot even in 10-feet lengths; but if Mr. Luckhurst will give me an order for 500 feet, I will supply him at 1*s.* 3*d.* per running foot, glass and all, and pay the carriage to his nearest railway station.

There is no comparison between wood and earthenware. Wood in boards would warp and split; wood would only last a few years, and then it must be well painted, not with two coats, as he suggests, but with at least four coats. The glass could not be fixed except by a glazier, unless, as I said before, he nullifies the patent laws. On the other hand, earthenware is, as I have shown, much cheaper than wood; the earthenware protectors are most durable, they do not require any paint or putty, the glass can easily be replaced without any skilled workman, the ventilation is perfect and complete, and, above all, the tiles retain the heat of the sun, which is slowly given out at night. I think I have said enough, and if your correspondent will only take the trouble to try them, he will find that all I have said is true.

In conclusion, will you allow me to say that I shall be happy to send a single 10-feet length to anyone who may wish to try the new system? and I am convinced that we shall be able to compete with the foreigners, and produce all kinds of early fruits and vegetables as easily and economically as they are enabled to do.—W. Edgcumbe Rendle.

ONCIDIUM ROGERSII.

The genus Oncidium is a very extensive one, abounding in an immense number of small as well as large-flowered species. The former, however, have not found much favour with the majority of Orchid-fanciers; neither can this be wondered at when there is such a vast number of really fine kinds which give double the amount of pleasure for the same outlay of trouble and care. Amongst the many fine forms of this genus which have been introduced to our gardens the one now under consideration certainly stands in the front rank, a formidable rival to even the majestic O. macranthum.

Oncidium Rogersii is a native of Brazil, but from what part of that country I am unable to say. It was introduced by Dr. Henry Rogers, of East Grinstead, in whose stove it first bloomed. It has hitherto flowered in the autumn months, but from the fact of so few specimens existing in this country, and its native habitat being unknown at present, the exact time of its flowering cannot be definitely stated. In general appearance O. Rogersii resembles O. bifolium, but upon a gigantic scale, for in the present plant the growths are as large as a pigeon's egg, and bearing upon their summits a pair of somewhat stout dark green leaves, whilst the black markings which are so characteristic of O. bifolium are found also upon the pseudobulbs of this plant. The flower-spike attains a height of about 2 feet and is much branched, bearing in the case of the specimen from which the accompanying figure was taken seventy of its brilliant flowers (A being one of the natural size), whilst other plants have produced spikes bearing as many as 170 blooms. The sepals and petals are very small, bearing indeed about the same proportion to the lip as do those of O. bifolium to the lip in that species; the lip is flat and spreading, deeply two-lobed in front, rich golden yellow in colour, and measures from 2 to 2½ inches in diameter.

It appears to thrive in the same temperature as Lælia purpurata and other similar plants, and grows admirably in a basket suspended from the roof of the Orchid house, potted in good peat and sphagnum moss, with the addition of some charcoal for drainage.

This truly grand plant is at present solely in the possession of the Messrs. Veitch, the eminent nurserymen of Chelsea, which is a sufficient guarantee for its being carefully preserved and

increased to meet the eager demands which are sure to be made for it as soon as it shall have become known to the Orchid world.—Experto Crede.

CLIMBING FERNS.

The Lygodiums are slender but fast-growing climbers; their foliage is particularly light and graceful in appearance. They so quickly make specimens, and have such a chaste and beautiful appearance, that I have often wondered they are not more generally grown. They are of scandent habit, admirably adapted for training up the rafters, pillars, or walls of ferneries. I grow some of mine a yard high, in the shape of a pyramid, and they have a most charming appearance when placed here and there about our fernery. Others I grow in baskets suspended from the roof. I have had them quite 3 feet in length, growing downwards, and as compact as when they have a pole to climb up. Some I have up the rafters of the house. Grown in either way they command attention. Some of them are noble climbers, and as such, I think, have been too much overlooked by cultivators. With ordinary care they become very luxuriant, and have a most picturesque effect. I have some which I shall shift into 1-sized pots shortly. I give them plenty of drainage; I put a large piece of crock over the bottom of the pot; I then put a layer of sandstone and charcoal; on this crocks broken very finely, then the compost—peat, loam, cocoa-nut fibre, and silver sand. In this they succeed extremely well, and have well repaid me for the care bestowed on them.

Lygodium scandens, a most lovely Fern from the East Indies, is a very fast grower. I have, in a 12-sized pot, a specimen 3 feet high, hanging over the edge of the pot and running up to a point. It would go higher if required.

Lygodium flexuosum is a very beautiful species, also a native of the East Indies.

Lygodium palmatum comes from North America, and is a lovely Fern; I have a beautiful specimen of it. To-day I thought, when looking at it plunged between Nothochlæna aurea and Cheilanthes elegans, what lovely contrasts they formed.

Some Ferns are sub-scandent in habit, and Selaginella cæsia arborea is one of the handsomest and most distinct creepers ever introduced to the Fern house. I have grown this variety as a pyramid to 6 feet high; I have also had it growing at one end of my stove, which it very soon covered. It requires to be shaded from the sun.

Sclaginella lævigata is a most splendid climber, the foliage is of a bright lustrous blue, especially when not exposed to too strong sunlight.

Selaginella cæsia makes a most beautiful specimen. I have grown it in my Cucumber house, and I have seen it at our shows, 7 or 8 feet high.

I have invariably found these gems well repay one for the care bestowed on them; they are very cheap, and I have noticed, in showing anybody round, that these were the first to be remarked. From their style of growth, they form a very pleasing relief placed at intervals in stoves or ferneries.—F. P. L.

Mr. William Barnes.—This well and long-known successful cultivator of plants died on the 22nd inst., aged nearly sixty-one. He was at one time head gardener to Mr. Haubury, The Poles, Hertfordshire, and carried off many prizes for the plants he exhibited at the Chiswick shows. Eventually he became a nurseryman and florist at Camberwell, where he died. He was brother of Mr. J. Barnes, until recently the head gardener at Bicton.

WORK FOR THE WEEK.

KITCHEN GARDEN.

All unoccupied ground should now be turned-up by rough digging, trenching, or ridging, regulating these operations according to the nature of the soil and the character of the preceding and contemplated crops. This is, however, more a month of preparation than of active operations, and much will depend upon the state of the weather. All sorts of work which can be done under cover should be well forwarded in bad weather, and hard frost will afford opportunities for wheeling all sorts of manures and composts. Look sharply after *Cauliflower* plants under hand-lights, as well as *Endive*, *Lettuces*, and *Radishes* in cold frames, protecting them with straw or reed covers, or spruce branches. If not already done seize the earliest opportunity of mild weather to sow a crop of *Peas* and *Beans*, choosing established early varieties. Some of the strongest roots of early *Rhubarb* might be covered with pots or boxes, and sufficient leaves and litter from the stable to produce a gentle warmth; this would save injuring the roots by removing them for forcing, but where there is a good stock of roots this is of little importance, and is hardly worth the trouble and litter which it causes. Prepare ground by heavy manuring and trenching for fresh plantations of *Asparagus*, *Rhubarb*, and *Sea-kale*, and remember that the ground for them can hardly be made too rich.

FRUIT GARDEN.

Pruning orchard trees will now require attention. It is a matter too frequently neglected, and the result is that the heads of the trees become so crowded with wood that a crop of fruit, except on the extremities of the outer branches, cannot be expected, and the thicket of worse than useless spray which the trees have to support, is injurious both to the size and quality of the fruit, as well as to the general health of the trees. Where this state of things has been permitted to exist, advantage should be taken of the first opportunity to give the trees a careful pruning, thinning-out the inner branches severely. In the case of large branches being cut off, the surface of the wound should be neatly trimmed-off with a sharp chisel and covered with a coat of paint. Persevere while the weather is mild in forwarding all necessary operations as regards wall-fruit trees, such as pruning, nailing, dressing, &c. Continue the renovation of old borders as opportunity offers. See that pyramid and bush Pear and Apple trees have the necessary pruning, and dress orchard trees with quicklime to destroy moss. The most effectual cure for this, however, is thorough drainage. Push forward all kinds of wheeling while the ground is in a proper state. Soils of a heavy character are improved by working and exposing them to frost.

FLOWER GARDEN.

During changeable weather like the present, little can be done as regards the regular work of this department, but where alterations are contemplated—such as making new walks, new flower beds, or renewing the soil of old ones—they should be forwarded whenever the weather will permit. Holes for planting choice shrubs or trees may also be prepared by removing the bad soil and replacing it with a compost suitable for the plants, and even where trees are planted and not growing well, the soil may be carefully removed from the roots and replaced with better material. Should frost set in cover Auricula frames with two good mats, giving air by tilting the lights whenever possible. Should the plants at any time be frozen allow them to thaw gradually, without being exposed to the action of the sun's rays. Those who have not obtained the necessary number of Ranunculuses to make up their beds, ought to do so without delay, as the period for planting will soon arrive. If the beds have not been already formed, perhaps the simplest and best way is to excavate the soil 2 feet deep and put in 6 inches of decayed cow dung, covering with maiden turfy loam to the depth of 12 inches, the remaining 6 inches to be equal parts of loam, leaf soil, and sand thoroughly incorporated. In the reserve garden, beds containing autumn-sown annuals would be the better of having a few branches of evergreens stuck into them to shade the plants from bright sunshine after frost, which has often a very injurious effect, and to protect them from drying winds.

GREENHOUSE AND CONSERVATORY.

Where proper means are allowed, the conservatory should soon be becoming gay. Chinese Primulas, Daphnes, early-flowering Heaths, and similar plants, which should be in flower, make a good display. Large plants of Rhododendrons or Camellias that have been some time in their pots or tubs, will require more attention than is generally given to them. Weak tepid liquid manure may be afforded them occasionally with advantage. In addition to keeping the conservatory gay with blooming plants, let the arrangement of the house be occasionally changed by grouping the plants somewhat differently, and adding a few striking ones for effect. Hyacinths should be protected by a frame; as they begin to grow remove the plunging material down to the surface of the soil to prevent them rooting upwards. Mignonette will require attention to keep it from damping. As with the exception of forced plants most other things are now in an inactive state, the temperature of plant houses should fall to its minimum point consistent with the safety of the various inmates; as has often been insisted on, hardly anything can be worse for the de-

velopment of a healthy vigorous growth in plants, than subjecting them to a high temperature at the present dull season. Where Achimenes are required to bloom early, a few pots may now be started for that purpose. About 40° will be a good temperature for the conservatory when not attached to sitting-rooms, and used for the purpose of wintering large specimens without plants in bloom; but where a supply of stove plants in bloom is constantly kept up from a forcing-pit, which is absolutely necessary in every large establishment in winter, the best heat is 45°. Cinerarias, which are great ornaments in this house in winter, are thirsty plants, and should be well attended to with water; they are also liable to the attacks of insects, and must be well looked after. Chinese Primroses are likewise very ornamental, and ought to be cultivated in quantity. As regards soil, two parts of rough leaf mould, and one of well-decayed cow dung, with a little sand, suits them best, and in this they like plenty of moisture.

STOVE.

All stove plants should now be quite at rest, and in that state 55° is quite high enough for them in cold weather. No more water should be given at the roots than will keep the leaves from flagging, but the atmosphere should be kept more or less moist. A high and dry temperature is much more injurious to stove plants than any cold they can suffer in a temperature above 45°. The usual mode of inducing shy-blooming plants to produce flowers is to cramp their roots. We have no such control, however, over Orchids, for if we confine their roots we disarrange their economy, and endanger the existence of the more delicate kinds; but as most of them will exist in a dormant state for many months, if moisture be withheld from their roots, we can compel them to alter their natural time of growth to suit our seasons; spring and autumn growth should, therefore, be discouraged by this means with all the shy-blooming kinds. The experiment should commence now by keeping them as cool and dry as they can bear for about six weeks, and in spring by increasing the heat as the season advances, but still withholding water till early in the summer, and then giving it only when their buds are ready to start. Young Stanhopeas are more difficult to flower than established plants, because they are more susceptible to changes of temperature or moisture. At this stage they may be made to grow in any month of the year. From now up to the beginning of May give as little water at the roots as is consistent with the health of the plants, and up to the middle of February 55° will be the proper temperature.—W. Keane.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Weeds, Refuse, Decaying Vegetables, &c.—We have several times, as a mere matter of profit and loss, advocated the fermenting and partially decomposing all rough vegetable matter instead of burning it. In the latter case the various salts which remain after combustion are the chief fertilising substances left, and though they go in little space and act more quickly, we do not consider that for land in general they can act as fertilising agents, and in heavy land as mechanical agents, in an equal degree to such material after it has passed through a process of fermentation and partial decomposition. We can see a case in point before us every day, and would wish that our readers in general, and our agricultural readers, amateur or otherwise, in particular, would note and turn their attention to it, and either approve or give their reasons for disapproval.

No good cultivation can be carried on whilst the land is permitted to carry a crop of *couch grass*, and other rough grasses and weeds, as what supports them takes so much nourishment from the cereals which we grow for our own support, and the sustenance of domestic and farm animals. The best mode of clearing such land of couch and other grasses we do not advert to; the best time is when the land is under fallow, or under preparation and tillage for a Turnip crop, as it is next to waste time and seeds to sow Turnips in uncleaned, unworked land. It is to what is made of the large quantities of such couch grass frequently obtained that we would draw attention. Generally by harrows, forks, and baskets it is collected, with more or less earth adhering to it, in heaps, and then is burned and the ashes spread on the ground, the ashes being chiefly valuable for the alkalies contained in them; and on stiff land the soil will be more benefited by the burnt earth, or quite as much as if the same quantity of sharp sand had been added. Now, in the case to which we refer, innumerable cartloads of creeping-rooted grass had been carted off the land and piled in a huge heap; drainings from the dung and the farmyard had been poured on it, a little farmyard manure and quicklime were added and mixed with it—a little salt would have done no harm—and now, when this huge reeking fermenting heap is being turned over, it is easily seen that every bit of the couch grass will be killed and a great amount of manure obtained, only inferior to that which comes from stall-fed fattening oxen, &c., under cover. We consider that for obtaining a large heap of fertilising manurial material, this is about the best mode of turning a bad enemy into a good friend. What say our practical readers? We yearly burn what is noxious, but so far as ultimate economy in fertilising material is concerned, we think it is better to char prunings, twigs, &c., than to burn them, and that it is better to take vitality from weeds, annual and perennial, by giving them a high temperature from fermentation and decomposition, instead of burning them.

During autumn, winter, and spring, in the garden of the amateur, the cottager, with his garden close to the cottage, and in the plot of the allotment-holder, it is very common to see heaps of vegetable refuse, weeds, &c., burned into ashes, and that where manuring material is very scarce. In many villages little manure can be obtained, except what comes from the cottage and the garden itself, as for reasons into which we need not now enter many proprietors and farmers object to their workpeople keeping a pig, one of the best of good manure-makers. Under such circumstances, the cottager with his garden contiguous to the cottage has a great advantage over the holder of an allotment at some distance, as he can make so much better use of everything in the way of dust, sweepings, slops, &c., from the house, and weeds and decaying matter in the garden. We have been glad to see such a burning heap of Cabbage stumps, haulm, weeds, &c., as that was much better than having them lying about polluting the air with their gradual decay; but we could not help thinking that the ashes thus obtained were a poor substitute for a nice heap of decomposing material, the enriching properties of which had been prevented escaping, whilst much of what was fertilising could be added every day in the way of dust, suds, and slops. However the most fastidious may dislike dirt in all its forms, we should not forget that it becomes valuable when kept in its proper place, and put to its proper use. Such a dirt heap should be at a considerable distance from the cottage, if not at the farthest end of the garden. When there is no heap, a sunk barrel or a hole well puddled should be made to receive all slops and dirty water, to be kept in reserve until there is a heap, or vegetables growing to receive it at once. Such a heap is best made in the form of a parallelogram, so that one end may be pretty well sweetened and decomposed before the fresh end has begun to ferment much. On this heap the slops from the house and the accumulated rich water may be frequently poured, and a sprinkling of earth over the place will keep in most of the good properties, and prevent them evaporating, or even tainting the air. Of deodorisers, dry earth is the best and cheapest. Having the heap at a little distance from the house is so far a disadvantage, as it involves more walking to it; but then it keeps all about the homestead sweet and clean.

Some time ago, on passing several blocks of cottage buildings, we had to use our handkerchief to shut up temporarily the orifices of our nasal organ, there was such a lot of strong-scented waters making a channel for themselves by the sides of the road. We looked over the fences, and did not see a single heap or hole in the grouped gardens. We could not help thinking that that water, decaying weeds, &c., would have added some 10 or 20 per cent. to the produce, and thus done good instead of being a nuisance. One word more and we have done for the present. We have alluded to a hole for saving the slops when they cannot well be applied to the ground or heap. Partly, no doubt, for this purpose, some careful cottagers make a good-sized hole, and everything, as weeds, stumps, haulm, as well as slops, &c., goes into it to decompose together. This is, no doubt, much better than doing nothing, but we do not consider it so good as forming a heap chiefly above ground; first, because much of the best properties of the heap are dissipated in the air; secondly, because if the watery part at all preponderates, you cannot by any process of dust or earth-sprinkling prevent unpleasant exhalations; and, thirdly, the material when dug out of such a hole, is not so sweet and mellow as when taken from a heap that has stood drier, and not been subjected to anything like a fœtid morass system. We

should, however, like to have the opinion of others more experienced in making the most of all such refuse from the house and garden. In this we shall all agree, that every weed that grows in a garden, when cut up, fermented, and decomposed, will help to give vigour and luxuriance to something more valuable. The chief point here to be guarded against is, that all seed weeds, with seeds approaching ripeness, should by heat or otherwise have the vitality of the seeds destroyed, or along with the means of increased fertility we may, in the number of perfect seeds taken back to the ground, give ourselves extra labour in eradicating them. The seeds of Groundsel, Thistle, and some other weeds, are not easily killed in a fermenting heap, and if the seed in these is formed, though not half ripe, it is safest to take the tops to the burning heap. A good strong plant of Groundsel just showing flower, if merely cut up and left in a shady place, will often perfect its seeds.

Remembrancers.—It is a good thing for us that the year is divided into so many landmark periods, as thus our habits of observation are brought into play and quickened. Many a garden receives an extra clear-up, that all may be nice and clean at Christmas, and the New Year. Many a cottager who would be ashamed of such things in May and June, is in danger of having decayed haulm, refuse, and plenty of weeds in his garden in winter. When we do anything well, we are apt to forget how long it has been done. A fresh-arranged house will be looked upon as a fresh-arranged house for weeks afterwards; it may be, when it ought to be freshened up again. It is sometimes desirable not to look at every thing and place too often. We then more easily detect what is amiss. What breaks in on the everyday monotony tends, therefore, to greater nicety, and neatness, and good management. An anxious amateur, then a bachelor, had his attention directed to the glass roof of his pet house. It required no shade, there was quite enough of slime and the lower forms of vegetable life. "Dear me! what a state it is in! There must have been an ill-natured magician here. It is no time since I had it thoroughly cleaned—not a spot left on glass or woodwork." But the *no* time honestly reckoned up, turned out to be fully twelve months, and during that time, if our friend thought at all of his glass roof, he thought of it as fresh-cleaned. If a certain fair-haired fairy had merely hinted the honour of a visit, would not the glass, plants, walks, grass, and everything out of doors and in-doors, had a regular inspection and cleaning? We fear that without breaks and spurrings-up, many of us would be too like our friend with his glass. Work done to-day is too apt to be looked upon as done for days, weeks, and even months afterwards.

Earthed-up Cabbages, put dung over Asparagus in rows, and protected Cauliflowers and salading. Placed more Sea-kale and Rhubarb in heat; the first gatherings from pots were very good. Watered the Mushroom bed with cow dung water as previously stated, spawned another piece, and laid the earth on loosely at first. Kept up successions of small salading, protected Broccoli where forward, sowed Radishes and Carrots on a slight hotbed, and set a number of Potatoes in small pots on a slight bed in the Mushroom house, to start them, and to be transferred when several inches high to frames. Mice are our chief enemies to Strawberry plants, Endive, and Cauliflowers. Much against our will, we have been obliged to poison a number of them. It is bad policy to use poison in any enclosed place, and especially in a dwelling house. A dead mouse which you cannot get at, is much worse than a living one, however mischievous.

FRUIT GARDEN.

Used great care in watering *Strawberry plants* swelling and ripening fruit, especially when manure water was used. As to plants beginning to move a little, too much care cannot be taken to keep the water from falling on or lodging about the crown or bud. It is bad practice to water in or at the centre of a pot containing a plant of any kind. It often ruins fine plants by causing gangrene or spot on the stem. It is safest in every way to sail the pot round the sides. One reason why many of our best old gardeners used to have the collars of their Heath plants raised considerably in the centre of the pot was, no doubt, owing to the difficulty of getting them watered without the water being lashed against the base of the stem. The same object can be attained with the plants no more elevated than usual, with good drainage, and careful watering, making the water flood round the sides instead of falling at the centre of the pot. Those Strawberry plants we have under old sashes have just the smallest amount of bottom heat, and plenty of air in mild weather. In all *forcing* it is best to give time, and allow the rise of temperature to be very gradual. In such cases as Vines, Peaches, and Figs, after cleaning, &c., a little more moisture, either in the air, or by the slight use of the syringe, assists the buds to swell and break more regularly; but a week or two more time in bringing them to this state will not be time lost in our latitudes, where most of the processes of vegetation proceed very gradually. A gentleman well acquainted with cold northern latitudes, where almost immediately on the melting of the snow there is at once a rapid and even somewhat luxuriant vegetation, owing to the sun's power in the short summer, once asked us how it was that having heat at command we could not effect equally sudden transformations in our houses. We fear any reply we gave was far from satisfactory. We doubt if any reason could be given now much better than that "such a thing is, because it is," and experience proves that a sudden transition from a low to a high temperature is one of the best means of neutralising successful results as respects the forcing of fruit and flowers.

ORNAMENTAL DEPARTMENT.

We must refer the reader to last week for the general work of cleaning, planting, &c., the latter work likely to be stopped by frost and a rising barometer, but affording, if the frost continue, a good opportunity for carting, wheeling, pruning, cutting wood, and ice-collecting.

Calceolaria Cuttings in a cold pit are now beginning to root—quite early enough, as they will not stand quite such rough treatment afterwards, as they will need more light and air. Except where a mouse has nibbled a few, and a solitary spot where four or five close together have damped off from no assignable cause, and thus have left a few inches square empty, not a cutting has yet gone wrong, or shown signs of doing so. We should have liked as well if the general rooting had been a little later, as the plants must be kept stubbier afterwards, or they would injure each other before we could move them to temporary beds. Up to Christmas-day some beds of Aurantia multiflora which we had left out of doors were quite fresh and green, though they had had 12° of frost. How they will stand the present frost time will show.

The most forward Chinese Primroses are in full bloom, and then, and even in any case in dull weather, they are easily injured by drip, watering overhead, or even drenching the centre of the plant. Much trouble is frequently experienced with beginners in inducing them to water at the sides of the pot, so as to wet the ball without wetting the collar of the plant much or at all. In a cold house, where Grapes were hanging, we were anxious to have a number of small pots looked over, and a little water given, where needed, carefully with the spout of a small pot, but to anything but our satisfaction the standing ground was as much drenched, and the leaves as much wetted all over, as if a large watering-pot had been used with a rose, without the least idea of sparing the water. Such treatment as the above would scarcely suit anything in a low temperature, with, perhaps, the exception of Cinerarias showing their flower-stalks strongly. At all times this plant relishes a damp, cool standing place. A high temperature will cause it to bloom earlier, but a high temperature and a dry atmosphere, or dryness at the root, or very great dryness on the standing place, are fruitful sources of green fly and other evils.

Looked over cold pits and frames. The great enemy for December and the first part of January is *damp*, especially when frames such as ours are used, standing over old exhausted hotbeds, as damp is more likely to rise than when frames stand on raised solid platforms without any old decomposing material beneath them. Every bit of damped or decayed leaf should be carefully removed in a fine mild day, and all the air and sunlight possible given. In frosty days the airing should be very moderate, and chiefly at the back. The sunlight, with its heat, will not draw up the plants weakly. Plants set on ashes, &c., will need but little watering. Still the plants will want looking over; and when a few pots are rather dry, if the waterer cannot make sure of his hand so as not to give too much or spill any beyond the pot, it will be good policy to lift all the few pots out, water them outside, and when well drained replace them. After having cleaned and fresh arranged plants in pots in a frame, removing the dampish surface and replacing it with dry ashes to assist in securing a dry atmosphere, it is not the most pleasant thing to see a thoughtless wielder of the waterpot slushing them all over with a rose as if it were the month of June, and thus neutralising all the well-meant efforts to avoid too much damp. With a little of such care, plants in cold frames and pits are often less subject to damp than in low-temperatured houses, as the frames, &c., can be covered up in cold nights, and thus the plants will escape the

damping that arises from drip—the result of condensed moisture on the inside of the glass.

For similar reasons in all houses where there is a low temperature, say from 40° to 45° as the average night temperature, whilst care is taken that Camellias, Cinerarias, &c., should have enough of water, care should also be taken to spill as little on the floor and paths as possible. In general the vapour rising from the surface of the pots and floor will prevent anything approaching a too-dry atmosphere in the house. Even in nights of very severe frost it is often better to let the temperature of the house sink 5° lower, but so as to be safe, instead of raising the temperature at all above the average with fire heat, as the higher the temperature inside the drier will the air be, and the more greedily will it suck up vapour from every source, and then, as the greater the difference between the inside and the outside temperature, the greater will be the condensing power of the glass, and, consequently, if no means be taken to prevent it, the greater will be the amount of drip all over the house. From inattention to these facts, we have seen houses after a frosty night with the roofs dripping like a shower-bath. With some attention to these details, we had some fine Camellia blossoms as regularly marked all over from the drip from iron bars as if a painter had dotted them. A safe but comparatively low temperature inside, when it is very cold without, and care in not using an excessive amount of water in watering, are the simplest preventives to excessive drip from roofs, and thus economy in fuel and labour too are our best helpers. We are well aware of the importance in this respect of canvas covering to arrest the free radiation of heat from the glass; but, then, many of us are glad to have the glass without venturing to have these coverings, which prove very expensive.

We know the importance of double *glass roofs* in this respect, more especially when the air enclosed between the roofs is almost still and shut in, but that, too, has some drawbacks besides the extra expense. We are convinced that, united to the simple remedies referred to, a continuous sheet of glass without laps will be a great security from drip, more especially when by such a plan as that of Mr. Beard the glass has the means of safely contracting and expanding. But as the simplest plans will ever prove the best, we have little doubt that ere long comparative warmth and freedom from drip will be secured by using a lighter-coloured and much thicker glass, though this will involve the necessity of stronger roofs. As a general rule, it may be considered that in winter the heat thrown from a fireplace into a room sends about one-fourth of that heat through the thin glass of the window: hence the comfortable temperature when the shutters are closed. A much thicker glass, say a quarter of an inch thick, would act as a shutter, and be equally serviceable for light. Strong, thick, clear glass for roofs would admit the necessary light, and, to a certain extent, dispense with the help of canvas coverings and double roofs. This matter has not yet received sufficient attention, but it will no doubt do so, and already many are using 26 and 30-oz. glass instead of 14 and 15-oz. glass. The first expense, of course, would be greater.—R. F.

COVENT GARDEN MARKET.—December 29.

There is very little to be noticed here that is either new, useful, or curious; for we have been overstocked, and business has not been of a remunerative character. Fine Apples and Grapes continue plentiful, and among them are some fine examples for the season. Pears are sufficient for the demand; good Apples, however, are in request, the American Newtown Pippins realising high prices. The Potato trade is heavy, with large arrivals by rail.

TO CORRESPONDENTS.

*** We request that no one will write privately to any of the correspondents of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely to The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

N.B.—Many questions must remain unanswered until next week.

Sowing White Table Maize (*Y. E. B.*).—You may sow it in 4-inch pots, sheltered from frost, as your propose. Sow during March. Any moderately fertile garden soil will do. Sow 1 inch deep. Plant out in May.

Beech Scale Destroying (*A Subscriber*).—Dress the trees with paraffin oil now, applying it to every part with a brush. Clarke's compound, 3 ozs. to the gallon of water, applied at a temperature of 160°, will also destroy it.

Flue for a Forcing Pit (*G. A B.*).—You will see what Mr. Robson and another correspondent say about flues in our present number. Should you adopt the plan recommended by Mr. Robson, we shall be pleased to hear from you how it answers.

Helleborus fœtidus (*A Subscriber*).—This native of England is commonly called Bear's-foot and Setterwort. Any herbalist ought to obtain it for you, and any florist who advertises in our Journal can furnish you with the other plant you name.

Various (*R. Ll.*).—The pipes going through a tank, and covered with iron grating, will always secure you moist bottom heat. The pipes in a hollow or chamber will always give you dry heat, which you may moisten if disposed. But for the additional expense we would say, Have the tank. Either mode will give bottom heat to what you wish to grow in the pit, but when the roof is covered with Vines you will not be able to grow much in the pit permanently. The height of such pits is best regulated by what is to be grown in them, and ease of access thereto, say 3½ feet at back, and 3 or 2½ feet in front. The mode of having the front of the house supported on piers, with 2-feet openings, will answer very well. On the whole we prefer such openings to arches. A border inside as far as the pit will be advisable, and if beneath the pit with due openings we would not object. The stems of Vines should be 8 or 9 inches from the hot-water pipes. If nearer, place a thin board between them, or wrap the stems in moss, and let it be dry. You seem to have marked six Vines to each house, which we consider a good number. We are not sure that we understand your mode of training. What we would consider the best in such a house, would be merely taking the Vine up and across the house from 15 to 18 inches from the glass. For the earliest house, two Black Hamburghs, one Sweetwater, one Trentham Black, one Royal Muscadine, one Black Muscat of Alexandria (Muscat Hamburgh), and as you want a house all Muscats and Frontignans, say White Frontignan, Red Frontignan, or Black Frontignan, two Muscat of Alexandria, and two Bowood Muscat. But for having all Muscats, we would suggest one Lady Downe's, and one White Lady Downe's. The proposed shelf round the vineries, with the walk and pit in the centre, we consider good. Slate or sparred wood will be the best for shelves. Iron becomes quickly heated and cooled, and, what is worse, soon rusts. If, however, you should prefer iron, it is best to paint merely with oil. The centre of the conservatory would be a good place for a tank of rain water, but it should be covered over, with merely a suitable opening left, and of course there must be a pipe to take away the superfluous water. The proposed mode of arranging the conservatory, so far as a stage or platform in the centre is concerned, we approve of; but we think that having an earth border all round will do away with unity of effect as respects the vinery on each side. With regard to the shelf all round, and the heating pipes, we presume beneath it—this, we think, would be the best mode in the conservatory, as thus there is no difficulty with the heating pipes. With an earth border all round for setting plants and trees on, as well as growing them there, you would require to place the pipes in the middle of the house below the stage, or they could run in a chamber beneath an iron-grated pathway. We do not enter on the heating from one boiler opposite one vinery, and the conservatory between it and the second vinery, as we presume that has all been settled. It is a good plan to place wires across the house at the distance from the glass already specified, and also to have longitudinal wires connected with them, say 2 feet apart; the wire one-eighth of an inch in diameter, or even less, will be strong enough.

One Boiler to Heat Several Houses (*Florist, Devon*).—We have no doubt that you will save fuel by having one boiler for all your houses; but as you have already three boilers to four houses, unless your houses are well situated, you might lose as much as you would gain, as there is always a risk in having eight houses depending on one boiler, as, if anything happens in severe weather, where are you? This is of so much importance, that it is now common to have two boilers, one to work in general, and the other ready if any casualty should happen with the first. We think your 30-inch-long saddle-back boiler would heat your 700 feet of 4-inch piping, if you did not require a high temperature; but

if you did so, then the boiler would scarcely have power enough. There will be no difficulty in heating all your houses by one boiler, if the boiler be placed in the lowest position, and, as you state, the lowest heating pipe is a foot or more above the top of the boiler. One of the easiest modes to do this is to take one main flow and return from the boiler to the farthest house, rising all the way a little, and then take off, by valves, others to each house to heat as you wish. We have no doubt that placing two 30-inch saddle boilers together in one furnace, and connecting their flows and returns, would give you ample power for what you want; but still, keeping in view what is stated above, instead of placing these boilers end to end, we would place them side by side, and thus have two furnaces instead of one, with one chimney; the pipes connected as you suggest, but with the means of shutting off or putting on the circulation at pleasure. Then in ordinary weather one boiler would be enough, but when wanted you could use both, and having two you would be much safer. Where anything like forcing early, or a high temperature is required, we should not like your 30-inch saddle-back to do more than heat from 500 to 600 feet of piping; but the lower the boiler, and the higher to the farthest house, the more work it will do.

Herbaceous Plants (*Herbaceous*).—Of the list of plants you forward, some of them are incorrectly named, and the spelling of some very bad. All are perfectly hardy, and snitsble for a mixed border in the flower garden. The soil, we apprehend, is not very heavy, but, on the contrary, inclined to be sandy, and well drained. If the soil were heavy they would probably not succeed. Dianthus may mean a Pink, Carnation, or Picotee, but which we cannot say. Iberis Tenoreana, white, April and May, 1 foot. "Libtus" is, perhaps, intended for Lotus corniculatus flore-pleno, yellow, June and July, 1 foot. Spiræa japonica, white, June and July, 1 to 1 foot 6 inches. Linum flavum, yellow, 1 foot, June and July, requires protection in cold situations, and a well-drained soil. Saxifraga ceratophylla may be the "horned Saxifraga," white, 9 inches, May. Aubrietia deltoidea variegata, bluish lilac or pale purple, March and April. Cheiranthus Marshalli, orange, 1 foot, March, or earlier if mild weather. Alinm variegatum, white, 6 inches, June. Statice Gmelini, blue, 1 foot, July. Primula cortusoides, deep rose, 6 to 9 inches, May and June. Physostegia speciosa, pink, 1½ foot, July.

Cucumbers Unfruitful (*K. K.*).—It is remarkable that the plants have not shown fruit before this. Some plants unstopped grow a great length before fruit is shown. Something must be radically wrong, for though the stopping would have indnced fruit at an earlier stage, allowing the shoots to grow unchecked would not necessarily bring on the sickly state of the plants. We have known plants do well under the treatment you describe, but we should not like to trust to unstopped plants for fruit. Is the soil sweet? If the plants are healthy, cut them back to near the bottom of the trellis; but whether or no, we should cut them down, and at the same time raise plants. When you see the result of the cutting-back, you will be able to determine whether it will be better to retain the old plants, or remove them and plant fresh.

Old Kitchen Garden Seeds (*A Subscriber*).—Old seeds are so uncertain of germination, that we do not advise them to be nsed. The seeds which you have by you of last year's stock will almost all to a certainty grow if they were new, or of the preceding year's growth, when you had them. As you do not know how old they are, we cannot tell you which seeds will and which will not grow; but we advise you to take a dozen seeds out of each packet and sow them in pots, placing them where there is a gentle heat, and when the plants appear you will know which are good, and you can frame your seed list or order accordingly.

Sloping Bank (*B. B.*).—To mow it easily with a scythe, or for two persons to mow it with a machine, to look well, and not burn in hot weather, the perpendicular height, A to B, being 3 feet, B to C, the base, should be 6 feet. Slopes are generally made much more steep than that, but they neither look well, nor are well suited for the growth of the grass.

Lilium auratum Potting (*M. K.*).—The best time to pot is when the stems decay. In potting, take care not to injure the roots, picking away the old soil as far as possible without breaking the roots. Potting may be done now, but better a couple of months earlier. It should not be deferred until the plants are beginning to grow, as the roots are then active, and there is a risk of their being needlessly injured; still you may pot at any other time if care be taken.

Ink for Zinc Labels (*Idem*).—One drachm each of sal ammoniac powder and verdigris, half a drachm of lampblack, and ten drachms of water, make an indelible ink for zinc labels.

Glass for Frames (*Clericus*).—21-oz. sheet glass is not too thick for garden frames, it is the most suitable for the purpose; the third quality would not burn the plants.

Specimen Chrysanthemums (*Idem*).—We shall presume that you are in possession of well-rooted cuttings in March, with single stems only, and take out the point when 8 inches high. Pot them at first in pots 4½ inches in diameter, and when these are full of roots, and before they become very much matted, transfer the plants to 7-inch and then to 9-inch pots, or, if very large specimens are wanted, to 11-inch pots. Allow no suckers until the flower buds show, and stop the laterals when they have grown 6 or 8 inches, repeating it again in July. The pots should be set on ashes in an open situation, and be well supplied with water, not allowing them to flag from want of it. When the pots into which they are last put become filled with roots, water twice weekly with liquid manure, and gradually increase the frequency of its application till it is given every day. The shoots, as they advance, should be tied out as far apart as possible, to admit air and keep the plants well furnished. Upon the tying depends much of the beauty and size of the plants. It should be frequently attended to, and be continued until the plants show for flower, and then you can dispose of the shoots with regularity. Take care that the plants do not root through the hole in the pot. Allow them plenty of room to keep them from becoming drawn to one side. Use a compost of rich turfy loam two parts, and one part old cow dung or well-rotted manure, and to every peck add a quart of bone dust. Good drainage is necessary. Do not water with liquid manure after the flower buds are as large as a sixpence. Sprinkle the plants with water overhead every evening, and after the buds show, night and morning until these expand.

Snowberry (*Tyro*).—This hardy white-berried shrub common in old-fashioned gardens is Symphoricarpus vulgaris, a native of North America.

Camellia Culture (*Camellia*).—It is not advisable to repot and cut-in the head at the same time. Were the pot full of good roots we would advise an opposite course; but as the soil is bad, the plants so overpotted, and the roots in bad condition, first take away all the old soil possible, saving every piece of good root, and then repot in the smallest pot the roots, &c., will go into, draining well, and using equal parts of sandy fibrous loam and heath soil with about a third of silver sand, the object being to obtain good roots. Plunge these pots into a sweet hotbed that will give a bottom heat of 80 and a top heat in the house of from 50° to 55°, the first object being to secure good and fresh roots, and for this purpose the head should be kept rather cool and syringed to encourage the rooting. When you find the roots growing freely and strongly, and reaching the sides of the pots, then prune in the top likewise, and gradually raise the atmospheric temperature to 70° or 75°, with atmospheric moisture in proportion. The mode you propose for taking water by means of a tap and small pipe into a gutter will answer, only if you wish the water to circulate in the gutter the return pipe at the farther end should communicate with the return pipe and not the flow. The gutter must be properly arranged for the purpose, or it will overflow if the tap be not nicely regulated. From the position of your pipe you might easily fill the gutter from the one pipe, and then shut the tap. Of course you would thus have hot water in your gutter at once, but so much cold water must be added to the main pipes and boiler. With gutters fixed on the warm pipes you will have plenty of evaporation by merely keeping them supplied with water.

Vine Shoots (*A Working Mechanic*).—We see nothing the matter with the wood, unless having rather too much pith. The wood is not large, but still it would bear well, as it seems firm, though we like to see little pith. The joints being without buds is a different thing, and that and the pith are most likely to arise from one of two things—want of drainage in the border, or want of moisture in a dry summer. With such a light border it would be well to mulch with something rich in summer, and if secure of drainage give the requisite moisture. You can have any back numbers free by post for 4*d*. If many were wanted you could order them through a bookseller, or have them sent by rail. We can recommend the "Vine Manual," which you can have from our office for 2*s*. 8*d*. in stamps.

Cherries for South of Scotland (*A Poor Lady*).—The two standards should be Black Hearts, the pyramid Belle d'Orleans, and the wall tree Black Tartarian.

Names of Fruits (*R. Pinches*).—Your Pear is Arbre Courbé. (*T. R.*).—Your Pear is the Croft Castle. (*C. C. E.*).—2001, Dumelow's Seedling; 2004, Russet Sweeting; 2005, Federal Pearmain; 2006, Holland Pippin; 2009, Rymer; 2010, Royal Codlin; 2011, Tower of Glamis. Others unknown and in bad condition.

Names of Plants (*Foxgrove*).—The Conifer is Pinus Smithoana. There is a plant called Grislinia littoralis, but we cannot identify it without seeing a flower. (*Subscriber, Southampton*).—Chimonanthus fragrans. (*Doctor*).—Zygopetalum Mackayi. (*A. B. A.*).—We believe your supposed Fern to be Pedicularis sylvatica. Are not your supposed spore-cases so many patches of a small parasitical fungus? (*D. M.*).—Adiantum pedatum, Doodia lunulata, a Polypodium (send us a better frond). Davallia novæ-zealandiæ does well under greenhouse treatment, whilst among others to suit you may be named D. canariensis and pulchella. The plants known as Leucostegia immersa and L. pulchra, now included in the genus Davallia, are very beautiful and do well in a greenhouse. Ferns mature their spores at different seasons, each according to its species. Collect the spores as soon as matured, and sow immediately afterwards. (*Wm. S*).—1, Catasetum tridentatum; 2, appears to be Epidendrum dichromum; and 3, E. reiculare. (*Filices*).—1, Selaginella Braunii; 2, Pteris cretica albo-lineata; 3, Polypodium arcolatum; 4, Hypolepis tenuifolia; 5, Pteris cretica (typical form); 6, Nephrolepis exaltata. (*J. B.*).—We take your Cattleya to be a very fine form of C. granulosa.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending December 28th.

POULTRY, BEE, AND PIGEON CHRONICLE.

NOTES ON THE BRAHMAS OF 1869.

During the past twelve months I have received so many letters of inquiry on different points from readers of my communications on this breed some time since, under my old signature of "Nemo," that I have thought a few later notes may not be unacceptable. I do not go into personal details, but simply record my impressions of the progress and present state of the two varieties, as they appear generally to one who is at all events a careful and loving student of them both.

First, they are both making way. I have always regarded the Brahma, not as by any means a perfect fowl, or in all circumstances even the best; but still as, on the whole, the "Shorthorn" among poultry breeds. Time is justifying this. In numbers they now stand either nearly or quite at the head in most poultry shows.

During the past year the birds have perceptibly gained in size. When I formerly wrote, I had to ask that more attention should be paid to this point. Such a hint would not now be needed. Many birds have been shown this season really enormous. Mrs. Hurt's second-prize Dark cockerel at Birmingham weighed 11½lbs.; one of my own weighed 11lbs.; and I am sure there were at least a dozen over 10lbs.; one of the pullets weighed 9lbs. This could not have been said even twelve months ago, and I am glad to record that we are getting back to the standard of the grand birds formerly shown by Mr. Teebay. I hope yet to see a cock that shall weigh 20lbs.

Leg feather, too, is coming back, and I am glad to see it. Very often, no doubt, hocked parentage has been employed; but hocked cocks may be bred from without injury, if used with judgment and caution. In too many cases plucked hocks still appear; but I am glad to be able to say that the judges nearly always detect them now, and the fraud does not pay.

On the whole, I think the Light variety has improved the most during the past twelve months, probably because—Will Messrs. Pares and Crook pardon me, I wonder?—they stood in most need of improvement. They are larger, shorter on the leg, much better in feather, and infinitely better in combs. The cocks, too, show more of that intangible but valuable quality called "style." It is pleasant to see that some of this work has been done by new exhibitors, with ladies in the number. There never was a year I remember so many new names added to the best class of competitors in all breeds; and those of older standing whom they have beaten in the friendly fight, will be those who will bid them most hearty welcome to the poultry fancy. There will be "cutting" work in "Lights" next season.

I make two remarks on the Light variety. The first is, there is some approach to yellow in the cocks of late—let this be shunned. The second is, that it seems to me both breeders and judges are now looking after rather more stripe or colour in the cockerels than formerly. I quite agree, for plenty of marking is half the beauty of Light Brahmas. They are *not* White Cochins. I give my own impression from seeing the classes and the judging. I may be wrong, but breeders will do well to at least bear the suggestion in mind in analysing the judging for themselves, as all good breeders do, and, if I am found correct, to choose their stock accordingly.

Many of the Dark birds this year have shown too much length of leg. I would never be too particular about short legs in a cockerel. I like a fine bird to have legs, but I have seen a good many really beyond moderation. It is a dangerous fault, as I can say from personal knowledge, it leads to coarseness of flesh. Moreover, it is much harder to "breed out" than it is to bring in. I hope breeders will beware, and keep within bounds.

Fashions change, even in poultry, as I have often been amused to see. The brown colour in Dark pullets some exhibitors used to like, is just now quite "out of court," and even the light Silver-Grey has hardly been seen this year, while the "newest style for the season" seems to be what I may call a "dead grey." My own individual fancy has always been for the darker, rich, green-black pencilling Mr. Teebay used to breed; but I do not dislike this. Many of Mrs. Hurt's pullets show the dead grey colour to perfection. The splendid grass run her birds have does wonders for them, and they are hard to beat.

In Dark cockerels and cocks I have been almost pained to notice a most serious fault, in the shape of a nasty yellow tinge. It was disagreeably evident even last year, but this season has increased to a very great extent; the hackles and saddles of at least half the prize birds, instead of the beautiful silvery white we used to see, being of a dingy yellow, like a very dirty Canary. I did not precisely agree with Mr. Boyle in every point of colour, but he certainly did almost always show cockerels of a beautiful silvery white, which is only too rare this year. I venture to ask the attention of the judges to this great blemish, feeling quite sure that if not checked, one of the chief beauties of the breed will soon be lost, not to be easily regained. The yellow I speak of must not be confounded with the effect of the sun, which will tan all birds as the plumage gets old, but which ought to show little effect at this time of year. It is singular that the yellow in the cocks has come in simultaneously with the "dead" grey of the pullets; and it is worth inquiry whether there may be any connection. I am inclined to think not; but if there is, I venture to say, that to sacrifice the beauty of the cocks for the sake of the pullets will be found a great mistake. I only note the fault as a serious and unsightly one, asking the attention of both breeders and judges to check its increase.

White in the tail has also, I am sorry to see, much increased among Dark cocks, and I have a shrewd suspicion whence it comes. I think myself this fault should be *almost* a disqualification. I do not say quite, because to disqualify absolutely a fine fowl for anything but real deformity is always injurious. But it ought, in my opinion, to count seriously against a bird, and I would never keep a cock in my yard that showed it. Dorkings are never considered birds of feather; but certainly Brahmas are, the pullets being chiefly judged by their plumage, and if so, a fault so utterly disgusting as white feathers in a tail which should be all black ought never to be tolerated. It is worse, too, for the very strong tendency to be hereditary. The fault never in my knowledge occurs, except there has been a cross from a strain already tainted with it; and so far, I have been able to trace nearly every case to a cross more or less remote from the stock of one particular yard some years back. Let this induce breeders to be careful how they introduce it.

I only remark, finally, that there has been some tendency shown of late by a few judges to judge Dark pullets too much by colour alone. The Brahma is a breed which should have not only leg-feathers, but fluff and cushion, without which it is as inferior as a Cochin would be similarly deficient, although the conformation is, of course, quite different. I have seen, however, with regret lately, many pullets win prizes apparently for their colour, which had no more of either fluff or cushion than a Spanish fowl. This is an error especially calculated to mislead beginners who purchase prize birds; and with this caution, therefore, I conclude my notes on the more striking peculiarities I have observed in "The Brahmas of 1869."—L. Wright.

POULTRY-SHOWING.

Will you permit one who has hitherto been an outsider to say a few words on the most unseemly strife that has been going on for some time in your columns about members of committee showing, and about the whole subject of poultry exhibitions? "Fie, gentlemen!" I would say; "shame to bandy about such charges! Positively, it would seem from your statements that exhibitors, committees, and judges were all a company of the most arrant rogues going; and I could only hold up my hands in astonishment to see the snarling and ill feeling that pervaded the letters written." I know nothing of poultry-exhibiting. I once reared fowls and rejoiced in my yard; and I have now commenced again, and won my spurs at our East Ashford Show with a fine pen of Crève-Cœurs; but I declare the pages of the Poultry Chronicle are enough to frighten one from exhibiting—that is, if one believed the statements, which I honestly confess I do not. I do not think my fellow countrymen are such rogues. And now for the moot point of committeemen exhibiting. I do not think there ought to be a second opinion on this point. It seems a fine notion, forsooth—(mind, I am not a committeeman), that the gentlemen who are interested in poultry in a neighbourhood, and spend their time and money in organising a poultry exhibition, should be subject to the annoyances and inconveniences which are inseparably connected with such things, and then for some lazy *dolce far niente* neighbour, who will take no trouble and give no money, to come in and take off the prizes because those most interested in it were shut out. Who ever heard at

a flower show of any proposition for excluding committeemen there from exhibiting? If such were attempted, I know from long experience that there would not be a provincial show in the kingdom; and if this rule were adopted poultry shows would soon become things of the past.

But people are dissatisfied, and think there is unfairness. There are very few beaten men who can take a beating comfortably; they must tell you how their shoulders ache, how sore their back is, how very sharp the whip comes. I have seen something of this at flower shows. I have seen a man white with rage, not because he did not get a first prize, but because another received an equal first with him. Therefore I count these complaints as very little worth. There is one thing which people do not take into account, and that is the individual tastes of a judge. What I mean is this, that although there may be certain well-defined points which every judge must acknowledge, yet there is still a margin, in some classes at any rate, to pave the way to differences of opinion, and consequently differences in judgment. I would never think of questioning the honesty of a judge, although I might question his judgment, and I would never allow an appeal against his decision unless in a case of proved unfairness in the exhibitor.—D., *Deal.*

GAME FOWLS.

I THINK that the present breed of Game fowls as represented at poultry shows has degenerated in many ways from the old-fashioned breed. Many of the desired points cause the fowls to lose both pluck and constitution. A long snake-like head and a fine neck are necessary for prize birds. This has the effect, speaking phrenologically, of causing the Game bird to lose the organ of combativeness, for a thickish neck and a certain breadth at the back of the skull distinguish all fighting animals. Again, length of limb, in order to make the bird show in the pen, is sought after; and to attain this the weedy cockerels and pullets are saved—birds which have a tendency to be delicate, and so the constitution of the breed becomes weakened. The feathering must be very short, close, and thin, with a small tail. Now, to get the feathering short and thin it requires a slender type of bird, but on good stout birds it is easy enough to have the plumage short and close, but not thin. People who have been used to seeing good-coloured cockers' birds, when they see an exhibition bird on his run consider him an ugly long-legged animal; but the eyes of exhibitors and the judges have become used to the present type of bird, and if they see a good stout cockers' bird in a pen beside any exhibition bird it is thought a coarse bird not worth looking at.

The exhibition Game fowl has lost so much constitution that it is not a really valuable farmyard fowl, as the chickens are so delicate and difficult to rear. People say that sending birds to shows ruins the constitutions of the various exhibition breeds; but the true reason is, so many weak-constitutioned birds are saved for particular points, that in time the whole breed begins to lose its stamina. I think that if judges only judged them as the type of the old fighting birds, instead of mere cage birds, the birds would be hardier, more useful, and not less handsome. —CHARYBDIS.

A FEW WARNING NOTES.

"TRAVELLERS see strange things" is an old saying, and I may add, hear strange things. At Birmingham Poultry Show, in the yard and at the hotels, I met and talked with, and heard talk, many exhibitors—I wish I could say fanciers, but they were so few that I think it will not be a very wrong designation; for several of them in my opinion had no pretensions to such honour. I remember the time, and it is not so long ago, when men, and women too, kept poultry and Pigeons for the very love of them, looking at their beauties with delight, and priding themselves on the purity and excellence of their particular breeds—one celebrated for his gallant Game, another for his heavy Dorkings, another for his superb Cochin fowls. Then, again, the real Pigeon-fancier, who would exhibit with a glow of pleasure the birds bred by himself, and which no money would induce him to part with. But, alas! what did I hear at Birmingham? Where is the honour gone? Now it is all for profit, and money prizes, and cups. But in what way, too? I heard of borrowings and lendings, of buyings and sellings, of pluckings and weedings, of colourings and clippings, until I was fairly disgusted. Here are men getting prizes for borrowed birds, and soon after we see advertised, "Birds same strain as those which took first prize at such and such a show." Then there is a cup offered, perhaps, at certain shows for the winner of the greatest number of prizes in the poultry, and another in the Pigeon classes. Where do these go to? Why, to the one who can and does borrow the most birds in many cases, and so the good (though not overstrong as regards numbers in the way of varieties) fancier goes to the wall. It ought to be worded in the schedule of prizes, "A cup to be awarded to him who can *borrow* the most birds."

But, as I have said before, the mischief does not end with the show, for other birds are sent out often from the yards and lofts of those exhibiting, with a statement that they are of the same strain as those exhibited—in poultry I may add eggs—when in reality they are no relation whatever, but often bought for the purpose afterwards. I heard of one man whose birds took prizes and were claimed, and who straightway went and bought others and advertised them as "Having some birds left," &c. Said some true fanciers to me, "We shall give up showing if this sort of thing is going to continue." Speaking to one of the Judges, I asked, "Did you find any trimming this time?" "Why," replied he, "if all the feathers could be collected that have been drawn from the poultry and Pigeons shown I should have a respectable feather bed."

I have read much that has been written by exhibitors against poultry committees and judges; but it is my decided opinion that if they were not more earnest for the welfare of the poultry and Pigeon fancy than many of the exhibitors, poultry and Pigeon shows would soon come to a miserable end.

At Birmingham I heard that already men were beginning to lay plans for borrowing for the London Show on the 15th of January at the Crystal Palace; and I sincerely trust, and I earnestly hope, for the sake of the honour and well-being of the fancy and in justice to all, that these men will find—though they seek never so much—that these men will find no lenders.

I write the above "without prejudice," and it is addressed "to all whom it may concern."—BLACK DOMINO.

TO THE COMMITTEE OF THE LONDON POULTRY SHOW.

PRAY listen to my complaint. I am an ill-used bird. There are my pied cousins, Mr. and Mrs. Houdan, honoured by a separate class, while I am huddled in with any other French variety. Any other, indeed! Hear what my friend M. Jacques says of me in "Le Poulailler:"—"This admirable race produces certainly the very best fowls that appear in the French markets. Their bones are lighter; the flesh firmer, shorter, whiter than those of the Houdan. The Crêve-Cœur is the chief race in France for the delicacy of its flesh, the ease with which it is fattened, and its earliness; and I think that it is also the first race in the world from these points of view." And yet I am put in "any other class." I can say no more. My crest is up, my anger great, and I can only add that I am—AN INDIGNANT CRÊVE-CŒUR.

COMPETING COMMITTEEMEN.

I NOW understand what "ALIQUIS" meant to say in his former letter about local cups and the "contingency" connected with them. He states in last week's Journal that "the local cup is far beyond his (the foreign exhibitor's) reach by being made local." He ought rather to have said that the outside or foreign exhibitor is excluded from the local cup. The words quoted above have no other meaning. The inference, then, to be drawn from this is that in all cases where a local cup is offered there should be a general cup in the same class, to which the local cup stood second; otherwise, good birds from other neighbourhoods must necessarily be excluded also. Are local cups offered side by side with general cups as a rule? They are not. If they were, surely in the interests of poultry-breeding generally, and financially as regards shows, it would be more advantageous to give the money, which would otherwise be devoted to local cups, in cups for other varieties, in order to draw more entrance fees, more exhibitors, and finer birds. As for the honours of local cups, I have no sympathy with Tritons amongst minnows. As to the probationary use of local cups, the "contingency" mentioned by "ALIQUIS" of winning both cups, shows that the All-England-cup is, after all, the test.

"AN AMATEUR," quoting my words, tries to turn them against me. He says, "To carry the idea a little further, a successful exhibitor also becomes a hireling of the committeemen on his receiving a prize in open and equal competition." Surely "AN AMATEUR" knows the difference between a fee and a prize, that the former is compulsory,

that the latter is not so. A fee is a stipulated payment of some kind or another for work performed, the fulfilment of which the labourer can enforce by law if his work has been properly done. But the competition for a prize implies no such engagement, neither can the competitor enforce the award of the prize to himself, even if he may have fulfilled the conditions attached to the prize which has gone to one less deserving. Without a wage and the condition of service inseparable from it, where is the hire? And without the hire, what becomes of the alleged hireling? If all men were honest, it would matter but little what position they hold; but as it is not so, there ought to be no vantage ground in competition, even if those having it will not condescend to use it. But if committeemen will claim that vantage ground amongst exhibitors in consideration of their services and expenditure, then they hire themselves to exhibitors for the inadequate wage, I grant, of the chance of obtaining prizes; and so, many become hirelings in the strict sense of the word, which the outside exhibitor can never be, even if he have the spirit of a hireling. Exhibitors unconnected with the official parts of shows are not more honourable than those connected with them. But this is no argument against my view. Opportunity may soon offer itself for strictures upon them quite as strong as those I have directed towards exhibiting committeemen.

"An Irish Committeeman" says, "If a committeeman in his capacity of unpaid official were precluded from exhibiting, he would have but two alternatives—namely, either to lose in a great measure the pleasure he has in producing good birds, or to resign his position as committeman." Surely the "Irish Committeeman" must mean that the committeeman has only one alternative, which offers the choice of two things, one of which only he can take as an alternative. But let that pass. I would not have noticed it had not the "Irish Committeeman's" letter assumed that he was settling the whole matter. My answer to his dilemma is this, that if the committeeman had no other show open to him he might have some appearance of reason in his complaint; but as this is not the case, he has not any sufficient reason for losing the pleasure of producing good birds. As well might a man say that he lost pleasure in bringing up his children, because he might not live to see the result. If, on the other hand, he covets the distinctions which a local show will afford, then I can see no hardship in his ceasing to hold an office which is arduous and expensive, and, I fear, often thankless. As to the likelihood of shows decreasing if committeemen ceased to compete for prizes, it must be remembered that the numbers of committeemen who compete for prizes is a very small minority, and that in proportion as shows increase it will become smaller, because the increase will afford committeemen greater opportunities of exhibiting their birds.

It only remains for me to remove an objection which has been urged by several of your correspondents who differ from me. It is stated that I cast a slur on the characters of committeemen and judges. Let me state most distinctly, that collectively I look upon both as painstaking, liberal, and honourable men, to whom exhibitors are much indebted. It is as absurd to say that I cast any slur upon the characters of committeemen and judges, as it would be to say that the recent reforms in the law by which clients are benefited are an insult to the reputation of lawyers.

Mr. Wright thinks that I felt the force of "An Old Committeeman's" supposed cases, and he puts them anew and in more definite terms. He supposes that at Birmingham Mr. Mapplebeck's and Mr. Tomlinson's Buff Cochins had been debarred from competition, Mr. Lane's Spanish at Bristol, and so on; and he concludes that an inferior standard of beauty will be held up for imitation. I certainly did not feel the force of these suppositions when they were first put, and I do not now, even when they are re-stated in more definite terms. The only inference I can see is, that those exhibitors who are unknown, and to a certain extent untried, would fear to venture against such tried competitors; and that, particularly in neighbourhoods where there is but one great breeder of any distinct variety, the standard would thus be lowered instead of being raised. When the race is easy the racer is apt to become careless, hence the great advantage of increasing the number of shows, and particularly large ones, such as Birmingham, Manchester, the Crystal Palace, &c., where local giants are not, by reason of their fame and strength, likely to have it all their own way.

Mr. Wright, speaking of the probability that if committeemen were excluded from competition they would resign their office, says—"I repeatedly notice that in most cases the withdrawal of a name from the ranks of exhibitors is followed by retirements from committees also," and he cites a case at Bristol this year. But this has nothing to do with the subject. It will not do to illustrate local cases by general instances. A committeeman is asked that he should not compete at his own local show, but is left free to do as he likes at all others. This is not excluding him from general competition, or causing him to cease to be an exhibitor: therefore, the inference which Mr. Wright would draw falls to the ground as applied to local exhibitors.

Have good judges, says Mr. Wright, and we shall have good awards. Of the two gentlemen he mentions, Messrs. Hewitt and Teebay, I will venture to say that they are not only good judges, but good, honest men. Speaking of them as judges, how could Mr. Wright be led to remark upon "the readiness of these gentlemen to oblige where they can?" There is, necessarily, so intimate a connection between the judges and the working committeemen, frequently a pleasant and social intercourse on the evening preceding the show—which I would not, however, see broken up—that the strongest and most Spartan will might be led to look with favour on birds, concerning which few exhibitors, however honest, would be capable of holding their tongues in a general chat on those subjects uppermost in their minds. This is coming to the root of the objection to competing committeemen. There ought not to be any opportunity to oblige. The very disposition to oblige is dangerous. In this sense Messrs. Hewitt and Teebay are, I have, no doubt, most disobliging. But it requires a very stern will and clear brain to keep out of the difficulty. Cases of positive fraud are, I hope, few and far between. It is admitted, however, on all hands that they do exist, not only in committeemen, but also in judges and exhibitors. Whatever removes the opportunity is most to be desired. At present I touch only one of the above classes, but I seek to remove the opportunity which exists there. Public judging will not do it. That would only increase the difficulty of getting through the already too arduous work which judges have; but private judging should be private, and no committeeman should, under any circumstances, accompany the judge or judges during their examination of the pens, and, above all, a competing committeeman.

Mr. Wright's suggestion for a set form of words charging committeemen and judges with unfair practices where these are supposed to exist, "simply to state the facts," as he calls it, must have been written in a hurry. In the first place, who is to make the charge? Who is to decide that the person making the statement is not ignorantly wrong or knowingly malicious? What is there in the *fact* that exhibitor A conversed with judge B which can be taken as evidence? And can the statement concerning prizes, "evidently not deserving them," be called a *fact*?

I will make a proposition to meet the case. It is this—Let committeemen exhibit at their own shows free of all expense, their pens being marked, "Not for competition." All that is contended for and required by your correspondents will then be obtained. A standard of excellence or beauty will be kept up. The exhibiting committeeman will have a pride in displaying his birds before those persons who will know very well whether they are better or worse than the prize birds. Exhibitors would appear before him who never would have appeared against him, and both might be benefited by the opportunities of comparison. Except in direct and secret fraud, over which the judge has an entire control, there could not be any unfairness in the awards. Committeemen would be beyond suspicion, and judges beyond the opportunity of "obliging."

It will require stronger arguments and more able advocates than have yet appeared to cause me to alter my convictions on the subject of competing committeemen, yet to those who have appeared against me let me hold out the hand and wish them in all sincerity a merry Christmas and a happy New Year.—Egomet.

[We think this controversy may now close.—Eds.]

DURHAM POULTRY SHOW.

The following are the awards made at this Show, held on the 21st and 22nd inst.:—

Dorkings.—1, J. White, Warlaby, Northallerton. 2, W. Bearpark, Ainderby, Northallerton. *Chickens.*—1, J. Shorthose, Newcastle. 2, J. White.

Cochins (Cinnamon and Buff).—1, G. H. Procter, Durham. 2, J. Shorthose. *Chickens.*—1, G. H. Procter. 2, J. Shorthose.

Cochins (Any other variety).—1 and 2, G. H. Procter.

Spanish.—1, H. Wilkinson, Earby, Skipton. 2, W. Elliott, Bishop Auckland. *Chickens.*—1, A. Wilkinson. 2, W. Watson, jun., Darlington.

Brahma Pootras.—1, W. J. Robson, Newcastle. 2, R. Moore, Hetton-le-Hole. *Chickens.*—1, J. Shorthose. 2, L. H. Ricketts, Banwell.

Game (Black-breasted and other Reds).—1, Buglass & Williamson, Carrville. 2, T. Horne, Tow Law. *Chickens.*—1, J. Watson, Knaresborough. 2, J. Wilson, Whitworth Woodhouse, Spennymoor.

Game (Any other variety).—1, J. Gibson, Stanhope. 2, J. H. Dawes, Birmingham.

Hamburghs (Golden-spangled).—1, W. Bearpark, Ainderby, Northallerton. 2, T. Mitchel, Mount Pleasant, Crook.

Hamburghs (Silver-spangled).—1, C. Armstrong, Bedlington. 2, G. Stalker, West Sleekburn, Morpeth.

Hamburghs (Golden-pencilled).—1, W. Bearpark. 2, W. Hall, Sleekburn.

Hamburghs (Silver-pencilled).—1, R. Parson, Morpeth. 2, T. H. Readman, Whitby.

Polands (Any variety).—1 and 2, G. H. Boothby, Louth. *Chickens.*—1, C. Walker, Boroughbridge. 2, G. H. Boothby.

Game Bantams (Any variety).—1, Bellingham & Gill, Burnley. 2, W. Dixon, Sunderland.

Bantams (Any other variety except Game).—1, G. Atkinson, Croft Station. 2, W. H. Tomlinson, Newark.

Ducks (Aylesbury).—1, W. Stonehouse, Whitby. 2, S. H. Stott, Rochdale.

Ducks (Any other variety).—1, E. J. Jones, Pasten, near Whitehaven. 2, S. H. Stott.

Selling Class (Any breed).—1, G. H. Procter. 2, T. Powell, Knaresborough.

Turkeys (Any variety).—1, Mrs. Turnbull. 2, Mrs. Minto, Hetton-le-Hole.

PIGEONS.

Tumblers (Almond).—1 and Medal, J. Fielding, jun., Rochdale. 2, F. Graham, Birkenhead.

Tumblers (Any colour).—1, J. Fielding, Rochdale. 2, F. Graham.

Carriers.—*Cocks.*—1 and 2, E. Horner, Harewood, Leeds. *Hens.*—1, E. Horner. 2, W. Massey, Spalding.

POUTERS.—*Cocks.*—1, E. Horner. 2, H. Brown, Walkeley, Sheffield. *Hens.*—1 and 2, E. Horner.
BARBS (Any colour).—1 and Cup, E. Horner. 2, J. Fielding, jun.
TRUMPETERS (Any colour).—1, W. B. Van Haansbergen, Newcastle. 2, E. Horner.
FANTAILS (Any colour).—1, E. Horner. 2, F. Graham.
JACOBINS (Any colour).—1, E. Horner. 2, W. B. Van Haansbergen.
TURBITS (Any colour).—1, E. Horner. 2, C. Vaux, East Boldon (Yellow).
OWLS (Foreign, any colour).—1, J. Fielding, jun. 2, W. R. & H. O. Blenkinsop, Newcastle-on-Tyne.

SELF-SUPPORTING.

OWLS (English).—1, H. Brown, Sheffield. 2, W. R. & H. O. Blenkinsop.
DRAGOONS.—1, J. Parnaby, West Sherburn. 2, J. Richardson, Seaham.
ANTWERPS.—1, G. Sadler, Boroughbridge.
TUMBLERS (Common).—1, J. Hawley, Bingley. 2, E. Horner.
BALDS AND BEARDS.—1, J. Fielding, jun. 2, F. Graham.
MAGPIES.—1, W. R & H. O. Blenkinsop. 2, F. J. Leach, Middlesborough.
NUNS.—1, W. Bearpark. 2, C. Vaux; F. Graham.
ANY VARIETY.—1, E. Horner.
SELLING CLASS.—1, J. Cundale, Ripon. 2, J. Robinson, Darlington (Nuns).

CAGE BIRDS.

BELGIANS (Clear Yellow).—1, J. N. Harrison, Belper. 2, J. Buglass,
BELGIANS (Clear Buff).—1 and 2, J. N. Harrison.
BELGIANS (Yellow, Variegated, or Marked).—1, J. N. Harrison. 2, J. Duglas, Stanhope.
BELGIANS (Variegated or Buff).—1, J. N. Harrison.
NORWICH (Clear Yellow).—1 and 2, J. Duglas.
NORWICH (Clear Buff).—1, R. Pearson, Durham. 2, J. Duglas.
NORWICH (Yellow, Variegated, or Marked).—1, J. Baxter. 2, R. Pearson.
NORWICH (Variegated or Marked).—1, J. Shield, Sunderland. 2, R. Pearson.
LIZARDS (Golden-spangled).—1, R. Pearson. 2, J. N. Harrison.
LIZARDS (Silver-spangled).—1, J. N. Harrison. 2, R. Pearson.
GOLDFINCH MULES (Mealy).—1, G. Shield. 2, J. Baxter.
GOLDFINCH MULES (Jonque-marked).—1, R. Pearson. 2, G. Shield.
GOLDFINCH MULES (Mealy-marked).—1 and 2, J. Baxter.
LINNET MULES (Marked).—1, J. Baxter. 2, T. Hardy.
CANARY MULES (Any variety).—1, R. Pearson. 2, J. Baxter.
GOLDFINCHES.—1, R. Pearson. 2, H. Nevison, Willington.
LINNETS.—1, H. Nevison. 2, J. N. Harrison.
BRITISH BIRDS.—1, T. Allenby. 2, A. Milne.
SIX CAGE BIRDS IN ONE CAGE.—1, R. Pearson. 2, J. Stephenson, Sunnyside.

JUDGES.—*Poultry:* Mr. R. Teebay, Fulwood, Preston. *Pigeons:* Mr. T. J. Charlton, Bradford. *Cage Birds:* Mr. T. Ridley, North Shields.

POULTRY AT THE GUILDFORD AGRICULTURAL ASSOCIATION'S SHOW.

THIS took place at Guildford on the 13th and 14th inst.

DORKINGS.—*Grey.*—1, E. May. 2 and 3, J. Ivery & Son. *Chickens.*—1, J. Ivery & Son. 2, M. Putney. 3, E. May. *c*, C. Pannell. *White.*—1, A. B. Friend. 2, G. Cubitt, M.P. *Blue.*—1 and 2, W. Franks. *c*, W. Belcher.
COCHINS.—1, J. Pares, Postford (Buff). 2, Curtis & Ashby (Buff.)
SPANISH.—1 and 2, F. James, Peckham.
BRAHMAS.—1, J. Pares (Light). 2, P. Crowley (Light).
GAME.—1, A. C. Crosse. 2, J. Pares (Black).
HAMBURGHS.—1, M. Reker (Golden). 2, J. Moon (Silver-spangled).
BANTAMS.—1, F. James (Game). 2, G. H. Gillam (Black Red Game). *hc*, J. Attlee (Black). *c*, — Martram (Duckwing Game); Curtis & Ashby (Game); P. Crowley (Black).
DUCKS.—1, J. Ivery & Son 2, Mrs. Norris. *c*, A. C. Crosse; M. Putney; E. Burge; Hon. F. Crosse; E. G. Austen. *Any variety.*—1, J. Ivery and Son. 2, Mrs. Norris.
GEESE.—1, W. Messenger. 2, Virgo & Son. *hc*, J. J. Stainton (Toulouse). *Goslings.*—1, W. Messenger.
TURKEYS.—1, W. Messenger. 2, J. C. Ramsden. *Poults.*—1, W. Messenger. 2, Countess Lovelace.
EXTRA PRIZES.—*Any variety not exhibited in the above classes.*—1, Rev. J. Chilton (Crève-Cœurs). 2, Hon. F. Scott (Houdans). *Dorkings* (White).—*Chickens.*—1, G. Cubitt, M.P. 2, W. Attlee. *Dorkings* (Blue).—*Chickens.*—1, W. Belcher. 2, W. Franks. *Dorkings* (Blue).—1, W. Belcher. *Dorkings.*—1, J. Ivery & Son. *Geese.*—1, Ivery & Son.

HECKMONDWIKE POULTRY SHOW.

THE eighth annual Exhibition of Poultry and Pigeons was held at Heckmondwike, on December 27th.

COCHIN-CHINA.—1, J. & F. Brooke, Huddersfield. 2, J. R. Walker, White Lee.
BRAHMA.—1, J. & F. Brooke. 2, J. Ledgard, Millbridge.
GAME.—*Black-breasted.*—1, J. Fell, Adwalton. 2, J. Wilson, Calverley, Leeds. *Brown Reds.*—1, W. Fell, Adwalton. 2, H. Beanland. *Grey and Blue Duckwings.*—1, W. Fell. 2, B. Naylor, Heckmondwike. *White or Piles.*—1, R. & H. Walker, Gomersal. 2, W. Carver, Southowram. *Black or Brassy-wings.*—1, J. Brooke, Gomersal. 2, R. & H. Walker.
HAMBURGHS (Oold and Silver-pencilled).—1, J. W. Wright, Cleckheaton. 2, Hainsworth & Fairbank, Farsley.
ANY OTHER VARIETY.—1, J. S. Senior, Dewsbury. 2, W. H. King, Rochdale. *Cock.*—1, J. S. Senior. 2, J. Fell. *Hen.*—1, H. Beanland, Bradford. 2, J. S. Senior.
BANTAMS.—*Red Game.*—1, G. Noble, Staincliffe. 2, C. Clegg, Heckmondwike. *Duckwing Game.*—1, J. Hirst, Heckmondwike. 2, J. Speddiog, Chickenley. *Black.*—1, J. Waddington, Guiseley 2, T. Parker, Preston, Heckmondwike. *White* (Any other variety).—1, J. Kay, Staincliffe.
PIGEONS.—*Antwerps.*—1, J. S. Senior. 2, E. Wharton, Hightown. *Owls.*—1, J. S. Senior. 2, J. W. Horsfield, Dewsbury. *Dragoons.*—1, J. Nutter, Cleckheaton. 2, T. Kilburn, Batley Carr. *Turbits.*—1, J. Kemp, Haslingden. *Fantails.*—1, J. Kemp. *Common.*—1, J. Parker, Heckmondwike. *Any other Variety.*—1 and 2, J. W. Horsfield.
JUDGE.—J. Dixon, Esq., Horton, Bradford.

FALKIRK POULTRY SHOW.

THIS was held in the Corn Exchange, Falkirk, on the 24th and 25th inst., and the following were the awards:—

SPANISH.—1, R. Somerville, Edinburgh. 2, W. C. Hardie, Carron. 3, J. Fergus, Polmont. *Chickens.*—1, J. Fergus. 2, R. Dickie, Alva. 3, W. C. Hardie.
DORKINGS (Any colour).—1, D. Annan, Cupar Fife. 2, A. Cowie, Airdrie. 3, M. Edwards, Hilton, Alloa. *Chickens.*—1, 3, and *hc*, T. Raines, Stirling. 2, M. Edwards.
COCHIN-CHINA (Any colour).—1, A. Campbell, Largs. 2, G. F. Lyon. 3 W. R. Park, Melrose.
BRAHMA POOTRA (Any colour).—1, J. A. Dempster, Stirling. 2, H. W. Peple, Perth. 3, J. W. Morrison, Kirkcaldy.
SCOTCH GREYS.—1 and 3, W. Gibb, Newarthill. 2, A. Johnston, Bathgate.
HAMBURGHS (Golden-spangled).—1 and *hc*, J. Jardine, Kilmarnock. 2, Mrs. Brown, Abercairney. 3, A. Robertson, Kilmarnock.
HAMBURGHS (Golden-pencilled).—1 and 2, A. Pratt, Kirkcaldy. 3, W. R. Park. *hc*, J. Richmond, Kilmarnock.
HAMBURGH (Silver-spangled).—1, R. Bruce, Busby. 2, D. Forrester, Linlithgow. 3, A. Penman, Cardenden, Lochgelly. *hc*, J. Watt Will, Errol.
HAMBURGHS (Silver-pencilled).—1, M. Bearpark, Northallerton. 2, R. Thomson, Kirkcaldy. 3, W. Gibb.
POLANDS (Topped).—1, Mrs. J. P. Proctor, Hull. 2, R. M'Nab, Cardonald, Govan. 3, A. Cowie.
GAME (Any colour).—1, R. Stewart, Kelty, Blair-Adam. 2, W. Chalmers, Leslie. 3, A. Erskine, Easter Shieldhill. *hc*, J. Blair, Blairingone.
CROSS OR COMMON BREED (Any colour).—1, G. F. Lyon. 2, J. Tod, Bowhouse. 3, A. Binnie, Grahamston.
ANY OTHER DISTINCT BREED.—1, J. T. S. Paterson (Houdan). 2, W. R. Park (Crève-Cœur). 3, J. Pollock (Malays).
DUCKS (Aylesbury).—1, J. Dod. 2, A. Robertson, Kilmarnock. 3, R. Dickie, Alva.
DUCKS (Any other variety).—1 and 2, A. Robertson (Ronen). 3, J. Wilson, Nicolton. *hc*, G. F. Lyon, Kirkmichael House (Muscovy).
TURKEYS (Any variety).—1, W. Forbes, Callendar. 2 and 3, J. Webster, Mungal Mill.
GAME BANTAMS (Any colour).—1, T. Raines, Stirling. 2, R. Brownlie, Kirkcaldy. 3, C. Peebles, Errol. *hc*, J. Robertson, Burntisland.
BANTAMS (Any variety).—1, R. Brownlie (Sebright). 2, J. Watt Will (Black). 3, D. Forrester (White).
SELLING CLASS (Any variety).—1, R. Dickie (Spanish). 2, W. S. M'Laren, Edinburgh (Buff Cochins). 3, J. Bow, Halls of Airth (Dorkings). *hc*, Mrs. Carswell, Stenhousemuir. *c*, L. M'Donald (Spanish).
PIGEONS.—*Pouters.*—1 and 2, A. Wright, Woodville, Morningside. 3, J. Morrison, Woodville, Morningside. *Carriers* (Any colour).—1, J. Bruce, Dunfermline. *Fantails* (Any colour).—1, J. G. Spence, Edinburgh. 2, W. R. Park. 3, W. C. Hardie, jun., Carron. *Jacobins* (Any colour).—1, J. G. Spence. 2, T. Paterson, jun., Melrose. 3, R. B. Heggie, Kirkcaldy. *Tumblers* (Short-faced).—1 and 3, J. Bruce. 2, F. D. Wood, Edinburgh. *Tumblers* (Long-faced).—1 and 3, F. D. Wood. 2, J. Bruce. *Any other Variety.*—1, T. Paterson, jun. 2, J. Morrison (Trumpeters). 3, W. R. Park. *hc*, C. S. Neilson, Falkirk (Barbs).
CANARIES.—*Yellow Cocks.*—1, J. Halley, Carron. 2, A. Cowie. 3, D. Slight, Grahamston. *Hens.*—1 and 3, D. Duncan, Carron. 2, A. Cowie. *Buff Cocks.*—1, A. Cowie. 2, A. Riddell, Carron. 3, W. Muirhead, jun., Alloa. *Hens.*—1 and 2, A. Cowie. 3, D. Slight. *Yellow Piebald Cocks.*—1 and 2, A. Cowie. 3, D. Slight. *Hens.*—1, W. Gilmour, Alloa. 2, J. Morrison, Alloa. 3, D. Duncan. *Buff Piebald Cocks.*—1, J. Halley. 2, A. Cowie. 3, D. Duncan. *Hens.*—1, D. Duncan. 2, J. Morrison. 3, A. Pearson, Abbotshaugh.

JUDGES.—*Poultry:* Messrs. M'Nab, Barrhead; J. Paton, Stewarton; J. M'Innes, Paisley; and M'Lauchlan, Paisley. *Pigeons:* Mr. J. Paton, Stewarton. *Canaries:* Messrs. S. Brown, Glasgow; and J. Robertson, Burntisland.

ABERDEEN POULTRY AND PIGEON SHOW.

THE first annual Show of the Aberdeen Poultry and Pigeon Association was held in the Artillery Gymnasium, Queen Street, Aberdeen, on the 23rd and 24th inst., and was very successful. There were upwards of 230 entries, and the following prizes were awarded:—

GAME (Any colour).—*Cock.*—1, W. Moir, Woodside (Brown Red). 2, 3, and *hc*, J. M'Pherson, Aberdeen (Black Red, Duckwing, and Brown Red). *Hens.*—1, W. Ewart, Stoneywood. 2, T. Skinner, Woodside. 3, W. Hay, Aberdeen. *Chickens.*—1, W. Anderson, Carnoustie (Ginger Red). 2, W. Ewart. 3, J. Donald, Granitehill, Rubislaw.
SPANISH.—*Cock.*—1, Mrs. Grassick, Colinton, near Edinburgh. 2, Mrs. Stronach, Sunnybank, Old Aberdeen. 3, G. Schaschke, Aberdeen. *Hens.*—Vase and 1 for best pen of Poultry shown, Mrs. Grassick. 2, F. M'Crae, Cunnigar Hill, Aberdeen. 3, A. Catto, Oldmeldrum. *hc*, Mrs. Stronach. *Chickens.*—1 and 2, Mrs. Grassick. 3, W. Fraser, Aberdeen. *hc*, T. Skinner. *c*, F. M'Crae.
DORKINGS (Any colour).—*Cock.*—1, Miss H. R. Lind, Ladiesford, Fraserburgh (Dark). 2, W. Fraser (Grey). 3, B. Ferrier, Woodside. *hc*, W. Snowie, Menymusk. *Hens.*—1, W. Fraser (Grey). 2 W. Snowie. 3, Miss H. R. Lind (Dark). *hc*, J. Simpson, Drigton, Durris. *Chickens.*—1, B. Ferrier, Woodside. 2, Miss H. R. Lind (Dark).
COCHIN-CHINA (Any colour).—*Cock.*—1, J. Calder, Aberdeen. 2, Mrs. Stronach. 3, G. Campbell, Tillinamalt, New Pitaligo. *Hens.*—1 and 2, J. Calder. 3, Mrs. Stronach. *hc*, J. Young, Aberdeen. *Chickens.*—1, J. M'Donald, Carnoustie. 2, W. Fraser. 3 and *hc*, Mrs. Stronach.
BRAHMA POOTRA (Any colour).—*Cock.*—1 and Prize for second best pen of Poultry shown, G. Robb, Bridge of Don, Aberdeen. 2, G. Davidson,

Bridge of Don, Aberdeen. 3. J. Johnstone, Aberdeen. *hc*, Mrs. Jeffrey, Woodside. *Hens.*—1 and 2, Mrs. Stronach. 3, J. Johnstone. *Chickens.*—1, J. M'Donald. 2, Mrs. Leighton, Baldarroch, Banchory. 3 and *hc*, Mrs. Stronach.

Hamburghs (Gold or Silver-pencilled).—*Cock.*—1, W. Abel, Persley (Golden). 2, G. Caithness (Golden). 3, W. Webster, Lower Middlefield, Woodside (Golden). *hc*, P. M'Robbie, Sunnyside, Aberdeen (Golden). *Hens.*—1 and *hc*, G. Laing (Golden). 2, Mrs. Stronach (Golden). 3, G. Campbell. *c*, W. Mearns (Golden).

Hamburghs (Golden-spangled).—*Cock.*—1 and 3, Mrs. Stronach. 2, Mrs. Brown, Abercairney, Crieff. *Hens.*—1, J. Still, Aberdeen. 2, W. Mearns, Aberdeen. 3, W. Abel.

Hamburghs (Silver-spangled).—*Cock.*—1, J. M'Andrew, sen. 2 and 3, Mrs. Stronach. *hc*, G. Caithness. *Hens.*—1, J. M'Andrew. 2, W. Grant, Aberdeen. 3, G. Caithness. *hc*, Mrs. Stronach.

Any other Variety.—*Cock.*—1, Mrs. J. M'Adam, Woodfield, Banchory (Houdan). 2, J. Marshall, Rosemount, Aberdeen. *Hens.*—1, Mrs. J M'Adam (Houdan).

Game Bantam (Any colour).—*Cock.*—1 and Medal, A. Dewar, Garlogie (Black Red). 2, J. M. Campbell, Bonnykelly, Newbith. 3, W. Soutar, jun., Udny. *hc*, E. Duncan. *c*, W. Hay, Aberdeen. *Hens.*—1, A. Dewar (Black Red). 2, F. M'Crae (Duckwing). 3, W. Hay. *hc*, E. Duncan.

Bantam (Any other variety).—1, Mrs. R. Frew, Sinclairston, Kirkcaldy (Sebright). 2, H. W. Pople, Perth (Black Red).

Ducks (Aylesbury).—1, Mrs. Cruickshank. 2, 3, and *hc*, Mrs. Stronach.

Ducks (Any other variety).—1, J. M'Pherson. 2, Mrs. Clark.

Turkeys (Any colour).—1, J. Duncan, Auchmilleddie, New Deer. 2, 3, and *hc*, Mrs. Stronach.

Geese.—1, Mrs. Dugnid, Ardmore, Udny. 2, Mrs. Leighton, Baldarroch, Banchory. 3, Mrs. Clark.

Selling Class.—1, L. M'Donald, Netherdurdie, Errol (Dark Grey Dorkings). 2, A. Catto (Spanish). 3, J. M. Campbell (Silver-spangled Hamburghs). *hc*, Miss A. Chalmers, Aberdeen (Brahma Pootra pullets). *c*, Mrs. M'Adam (Houdan).

PIGEONS.

Pouters (Any colour).—*Cock.*—1, F. M'Crae (Red). 2, Macgill Skinner, Edinburgh. 3, J. Sharp, Johnstone. *Hens.*—1, J. Sharp. 2 and 3, F. M'Crae. *Pair.*—1 and Medal, G. Schaschke, Aberdeen (White). 2, F. M'Crae (Yellow).

Carriers (Any colour).—1, M. Skinner. 2 and 3, G. Schaschke.

Tumblers (Almond).—1, Medal, and *hc*, J. M'Donald, Aberdeen. 2, F. Cooper, Arbroath.

Tumblers (Any other variety).—1, F. M'Crae (Blue Beards). 2, 3, and *hc*, J. M'Donald (Black and Baldheads).

Jacobins (Any colour).—1 and Medal, J. Sharp. 2, J. G. Spence, Edinburgh. 3, F. M'Crae (Yellow).

Fantails (Any colour).—1, W. Harper, Aberdeen. 2, W. R. Park, Abbot's Meadow, Melrose. 3, J. Sharp. *hc*, W. Soutar, junr., Udny. *c*, J. G. Spence.

Barbs (Any colour).—1, W. Harper (Black).

Turbits or Owls (Any colour.—1 and Extra prize, J. Sharp (Turbits). 2, A. Middleton (Owls). 3, W. R. Park (Turbits). *hc*, J. G. Spence (Owls). *c*, J. M'Donald (Turbits).

Nuns or Magpies (Any colour).—1 and 3, J. M'Donald (Nuns). 2, A. Catto (Magpies). *hc*, J. Sharp (Magpies).

Any other Variety.—1, 2, and *hc*, F. M'Crae (Blue Brunswick, Bluebeards, and Frillbacks). 3, J. Sharp (Helmets).

Trumpeters (Any colour).—Silver Medal, J. Sharp.

Pouters (Pied).—Medal for best pair of any age, F. M'Crae.

Oil Painting for the best pen of Pigeons, G. Schaschke.

Silver Medal to the most successful Competitor in Poultry and Pigeons Mrs. Stronach, Sunnybank, Old Aberdeen.

JERSEY POULTRY SHOW.

(From a Correspondent.)

Jersey, in the immediate vicinity of the cradle of the French breeds of poultry—Normandy, has just held its second Show. The entries for so small a place and the necessarily local competition, were numerous, being 359. This success is mainly due to the liberal prize list, and to the indefatigable energy of the Secretary, Mr. E. Pond. The prizes, on account of their small value, are no great temptation, but by adopting the policy of offering prizes for any breed which has once been shown and commended by the Judges, the Committee insure to every amateur in the island a fair opportunity of comparing the merits of his particular pets with those of others of the same kind. It is puzzling to know how the judges at poultry shows, where all the French breeds, Andalusians, Minorcas, Silkies, Malays, &c., have to go into the "Any other variety" class, come to a right conclusion, for not only can there be no comparison between a Malay and Crève-Cœur, or a Minorca and a Houdan, but the French breeds cannot, among themselves, bear the least comparison. How is it possible to compare a Crève-Cœur with a Breda or La Fleche, and a hope be justified that a fair award will be attainable?

The Show was held in the Vegetable Market, which is a lofty, well-ventilated structure, 80 feet wide and 188 feet long. Half this space lengthwise was boarded off for the Show, and gaily decorated with flags and evergreens. The pens were arranged in two single rows on the two sides, with a double row, and a single row on the top, down the middle. The Show in the evenings was well lighted with gas. The pens were supplied by Mr. Billet, of Southampton, and were all that could be desired, with the exception of those for Dorkings and French breeds, which were too small, and consequently showed the birds at a disadvantage.

The *Dorking* classes were poorly filled, but one or two of the Coloured Dorkings were very fine. *Cochins* were well shown, especially the Buff and Partridge. *Brahmas* were numerous and fine in both Dark and Light, and deserved more cards of commendation than were awarded, many pens of the highest merit receiving no award. The *French* breeds were well shown, the Black Crève-Cœurs, Houdans, and La Fleche deserving all they received. Black Bredas were not so good. In the "Any other French variety" the first prize went to Blue Bredas, second to White Crève-Cœur, highly commended to Blue Crève-Cœur. *Gueldres* shown in this class could not bear comparison with their opponents, though a high commendation would have done no harm, as they were perfect specimens. *Spanish* were not shown to advantage. *Andalusians* were badly shown, except the first-prize pen, which was first-rate. *Minorcas* were good; but here we come to the *crême de la crême*—viz., the *Game*, *Bantams*, and *Malays*. Not a bird in these classes but deserved notice, the Malays being especially fine, both the Dark and White varieties. *Hamburghs* were good. Among the *Polish* were some good birds.

Turkeys, *Geese*, and *Ducks* were very fine in all the classes. Fancy birds—Gold, Silver, Mexican and common Pheasants, Peacocks, Partridges, Quails, and a collection of Parrots, contributed not a little to the attractiveness of the Show. Ornamental Waterfowl comprised Sebastopol Geese, Wigeon; Wild, Carolina, and Buenos Ayres Ducks.

Pigeons and *Rabbits* were good but not numerous.

At this small local Show not only were the most numerous entries made by committeemen, but without them there would have been no show, and it would be impossible to find a committee to manage the Show without them, no one taking a sufficient interest. I must mention here an act of disinterestedness on the part of the Secretary, who is an ardent fancier, which I am far from thinking a necessity. All his birds were exhibited not for competition. Whatever he may have lost in prizes he more than gains in the good opinion of the other exhibitors.

The following is the list of awards:—

Dorkings (Any variety).—*c*, Rev. W. Lemprière, Rozel. *Chickens.*—1, E. A. Neel. 2, G. R. Ivimy.

Cochin-China (Cinnamon and Buff).—1, P. W. Le Quesne. *hc*, Capt. Robin. *Chickens.*—1, P. W. Le Quesne. 2 and *hc*, Capt. Robin.

Cochin-China (Brown and Partridge).—1, Capt. Robin. 2, P. De Gruchy. *hc*, R. A. Neel. *Chickens.*—1, Capt Robin. 2, J. Le Rossignol. *hc*, Capt. Robin; P. Gosset.

Cochin-China (White).—1 and 2, Capt. Robin. *Chickens.*—2 and *hc*, Capt. Robin.

Brahma Pootras (Dark).—1, Capt. Robin. 2, Lieut.-Col. Le Gallais. *hc*, P. W. Le Quesne. *Chickens.*—1, Capt. Robin. 2, P. W. Le Quesne. 3, Capt. Howell. *hc*, E. A. L'Oste.

Brahma Pootra (Light).—1, E. A. L'Oste. *c*, Capt. Robin; E. A. L'Oste. *Chickens.*—1, E. A. Neel. 2, E. A. L'Oste. *c*, Capt. Robin.

Crève-Cœurs (Black).—1, J. Ereaut, jun. *Chickens.*—1 and 2, Capt. Robin.

Houdans.—1, W. P. Le Quesne. 2, Capt. Robin. *hc*, J. Le Rossignol. *Chickens.*—1, P. W. Le Quesne. 2, G. De Faye. *hc*, P. De Gruchy.

La Fleche.—*hc*, Capt. Robin. *Chickens.*—1, J. Blampied. 2, P. De Gruchy.

Bredas (Black).—*Chickens.*—1, Capt. Robin.

French (Any other variety).—1 and *hc*, J. Ereaut, jun. 2, Capt. Robin.

Spanish.—1, Dr. R. King, sen. 2, P. Le Quesne. *hc*, Capt. Robin. *Chickens.*—1, Capt. Robin. 2, J. Pluck. *hc*, G. De Faye.

Andalusians.—1, T. B. Hutton. 2, Col. Le Gallais. *Chickens.*—2, J. Blampied. *hc*, G. De Faye.

Minorcas.—1, G. De Faye. *Chickens.*—1, J. Pluck.

Game (Black-breasted Red).—1 and 2, J. Voisin. *Chickens.*—1 and 2, H. Gibson. *hc* and *c*, J. G. Falle.

Game (Brown and other Reds).—1 and 2, J. Voisin. *hc*, J. G. Falle. *Chickens.*—1 and *c*, J. G. Falle. 2 and *hc*, J. Voisin.

Game (Duckwings and other Greys and Blues).—1, E. Gumbrell. 2, J. G. Falle. *hc*, A. J. Ronsseau. *Chickens.*—1, 2, and *hc*, J. G. Falle.

Game (Whits and Piles).—*Chickens.*—2, J. Voisin.

Malays (Any variety).—1 and 2, J. G. Falle. *Chickens.*—1, 2, and *hc*, J. G. Falle.

Hamburghs (Black).—1, Capt. Robin. *Chickens.*—1, G. De Faye.

Hamburghs (Golden-pencilled).—1 and 2, Capt. Robin. *Chickens.*—1, Capt. Robin.

Hamburghs (Silver-pencilled).—1, Capt. Robin. *Chickens.*—1, E. Tomkins. 2 and *hc*, Capt Robin.

Hamburghs (Silver-spangled).—1 and 2, G. De Faye. *Chickens.*—1 and 2, G. De Faye.

Polish (Black with White Crest).—*Chickens.*—1, G. De Faye.

Polish (Golden).—1, S. R. Delme. 2, J. Blampied. *Chickens.*—1, E. A. L'Oste.

Polish (Silver).—*Chickens.*—1, J. Le Rossignol. 2 and *c*, E. A. L'Oste.

Any other Distinct Variety.—1, E. A. L'Oste (Silkies).

Crossbreed.—2, Capt. Robin. *hc*, E. Pond.

Barndoor.—1, P. Gniton. 2, G. de Ste. Croix.

Bantams (Gold-laced).—1, J. Le Rossignol.

Bantams (Silver-laced).—*c*, Rev. Worth.

Game Bantams (Black-breasted Red).—1, P. W. Le Quesne. 2, Capt. Howell. *hc*, — Nicolle. *c*, E. A. L'Oste.

Game Bantams (Duckwing).—1, — Nicolle. 2, — Abererombie.

Bantams (Any variety).—J. Le Rossignol. *c*, J. Braddon.

Guinea Fowls.—1, — Dugdale. 2, J. Le Rossignol.

Turkeys (Black).—*Poults.*—1, — Denize. 2, — Dugdale.

Turkeys (Any variety).—1, P. Gosset. 2, E. A. L'Oste, *hc*, P. de Gruchy. *Poults.*—1, — Billet. 2, E. A. L'Oste. *hc*, E. A. L'Oste; E. Neel, jun.

Geese (White).—*Goslings.*—1, — Dugdale.

Geese (Grey and Mottled).—1, E. A. L'Oste. *Goslings.*—1 and 2, E. A. L'Oste.

Ducks (White Aylesbury).—1, J. Le Rossignol. 2, J. Ereaut, jun.

Ducks (Rouen).—1 and *hc*, P. de Gruchy. 2, J. Le Rossignol.

Ducks (Any other variety).—1 and 2, — Dugdale.

Pheasants.—2, Mrs. R. Gray.

Pheasants (Any other variety).—1 and 3, Mrs. R. Gray. 2, J. G. Falle. Extra Prize, P. Pinel.

Partridges.—2, J. Le Rossignol.

Quails.—2, J. Le Rossignol.

Ornamental Waterfowl.—1, J. G. Falle.
Ducks (Carolina).—1 and 2, J. G. Falle.
Ducks (Buenos Ayres).—1, J. G. Falle. 2, Miss C. Carey.
Ducks (Wild).—1, J. G. Falle.
Widgeons.—*hc*, J. G. Falle.

Pigeons.—*Carriers* (Any colour).—1, J. Le Rossignol. 2 and *hc*, P. W. Le Quesne. *Pouters.*—1 and 2, P. W. Le Quesne. *Fantails.*—1 and 2, J. Le Rossignol. *Tumblers.*—1, W. P. Le Quesne. *Jacobins.*—1, W. Hamon. *Owls.*—1, P. W. Le Quesne. 2, G. De Faye. *Runts.*—1 and 2, Capt. Robin. *Trumpeters.*—1, W. B. Dugdale. 2, J. Le Rossignol. *Nuns.*—1, J. Le Rossignol. *Frizzles.*—1, — Nicolle. *Any other Variety.*—1 and 2, J. Le Rossignol. 3, G. De Faye. *hc*, — Gregory; A. Hamon.

Rabbits.—*Lop-eared.*—1, A. J. Rossean. 2, G. De Faye. *Himalayan.*—1, Miss Pond. 2, G. De Faye. *Any other Distinct Variety.*—1, — Lang. *Any Variety.*—1, G. De Faye. 2, — De Carteret.

Judges:—Messrs. Falle, Pond, W. Godfray, Billet, Ogier, M. Gibaut, and J. Robin.

STOCKTON CANARY SHOW.

The institution of a new show should be noticed with pleasure by all lovers of the Canary. Stockton-on-Tees has made its effort, and a very praiseworthy one too, and has added its name to the now rapidly increasing list of "fixtures" of annual shows.

The Exhibition was held on the 18th inst. in the Temperance Hall, under highly influential local patronage. The entries were quite on a par with those of other shows in the same district, while the names of the winning exhibitors are ample evidence of the quality of the birds shown. There was but one thing to mar the pleasure of the proceedings, and that was the detection of a stained bird. In the execution of my duty as a Judge, and with a settled determination to expose such malpractices, I deem it right to make these matters public whenever they come under my notice. The bird in question was exhibited by Messrs. Layfield & Ellerton, of Darlington, but in justice to them I must say that the explanation tendered by them to me exculpates them from blame. I regret exceedingly to say that the deeper I stirred the investigation the more offensive became the effluvium, while the widely extending *tu quoque* circles of recrimination included in their area names which astonished me. I venture to express the hope, however, that we have seen the last of such doings. Let us not have our beautiful hobby defiled by the existence of such dishonest practices.

The Belgians stood first on the schedule, and I managed to get through them to the satisfaction of all present, notwithstanding Mr. Wallace's assertion that I am not a "proper person" to judge them. I do not see that because a man is not an enthusiastic admirer of any particular bird he cannot recognise its beauties. There are many things I can recognise which I do not admire; I can recognise unkind and ill-natured remarks, but I do not admire them. I should like to have passed an opinion on Mr. Bulmer's first-prize Buff Belgian hen; but what can I say? I do not want to hurt Mr. Wallace's tender susceptibilities. Shall I say she was a sylph? a fairy? a Venus? Well, so she was, but I mean a Venus "of the period," with a delightful "Grecian bend!" I do not like Belgians, I won't like them, but if ever I *do* invest, commend me to one like Mr. Bulmer's hen.

Messrs. Moore & Wynne's Jonque Norwich was a superb bird. In the Variegated Jonque class they showed a fine specimen, which being judged by a very dull light in the early morning, did not receive such an award as I should have given it later in the day, when its merits became more apparent. In "Variegated Buff Norwich" and "Dark-crested" birds, Messrs. Moore & Wynne were again unapproachable, though Messrs. Irons & Gayton were second in the latter class with a beautiful hen.

The Lizards were a very good sample, and included some respectable birds. Cinnamons were poor, excepting the winning birds, which were very meritorious. The Yorkshire were unsatisfactory, but the Variegated birds were very good. I wonder what Mr. Wallace means when he says he is *creditably* informed that "this variety of bird is unknown in Sunderland?" I think his informant makes a very dis-creditable statement; but Mr. Wallace having lived a lifetime in Sunderland, and knowing every fancier in it as intimately as I myself do, ought not to write as a stranger. However, I have no wish to disturb the placid surface of the pages of "our Journal" by personal remarks which can be of no public benefit, and will content myself with this comment on his strictures. "*Et tu, Brute!*"

Norwich Greens were again mixed up with the long pea green birds, I mentioned in my notice of Darlington. I still prefer to use the term pea green, albeit Mr. Wallace says there is no such colour in a Canary. To my mind it conveys a better idea than "black green" or "blackish green," though I find no fault with his definition. In the "Any other variety" class Messrs. Irons & Gayton were first with a very pretty evenly-marked and crested Cinnamon.

The Goldfinch Mules were a good class, and I think Moore & Wynne's dark Mule grows more beautiful every time I see it. Of Goldfinches, Linnets, and other British birds there were forty-nine entries, making a show by themselves.

The arrangements were excellent, and every attention was paid to the birds during the Show. I wish Stockton Show the success it deserves.—W. A. Blakston.

The following is the list of awards:—

Belgian (Clear Yellow).—1 and 2, W. Needler. 3, R. Robinson.
Belgian (Clear Buff).—1, W. Bulmer. 2, W. Needler 3 J. N. Harrison.
Norwich (Clear Jonque).—1, Moore & Wynne. 2 and 3, Pennock and Blackstone.
Norwich (Clear Buff).—1, W. Winter. 2, Pennock & Blackstone. 3, Moore & Wynne.
Norwich (Variegated Jonque).—1, E. Mills. 2, Pennock & Blackstone. 3 Moore & Wynne. *c*, T. Peat.
Norwich (Variegated Buff).—1 and 3, Moore & Wynne. 3, Irons and Gayton.
Canary (Dark or Grey-crested).—1, Moore & Wynne. 2, Irons & Gayton. 3, J. Taylor. *c*, Pennock & Blackstone.
Canary (Clear-crested).—1, Irons & Gayton. 2, J. Garbutt.
Lizard (Golden-spangled).—1, M. Barton. 3, W. Bulmer.
Lizard (Silver-spangled).—1, J. Fryer. 2, J. Taylor 3, M. Burton.
Lizard (Golden or Silver-spangled with broken cap).—1, I. Cherry. 2, J. Moses. 3, R. Hawmao. *c*, J. Leek.
Jonque (Cinnamon).—1, Irons & Gayton. 2, E. Mills. 3, W. Bulmer.
Buff Cinnamon.—1, E. Mills. 2, Moore & Wynne. 3, Irons & Gayton.
Canary (Clear Yellow Yorkshire).—1, J. Vale. 2, H. Ward. 3, M. Burton.
Canary (Clear Buff Yorkshire).—1, J. Garbutt. 2, H. Garbutt. 3, H. Ward.
Canary (Variegated Yellow Yorkshire).—1, J. Leek. 2, J. Taylor. 3, M. Burton. *c*, A. Brown.
Canary (Variegated Buff Yorkshire).—1, J. Taylor. 2, A. Brown. 3, M. Burton.
Canary (Clear Green).—1, M. Burton. 2, H. Jerrison. 3, R. Fidler.
Canary (Any other variety).—1, Irons & Gayton. 2, Moore & Wynne. 3, T. Armstrong.
Collection of Six Canaries in Variety.—1, R. Caugbey. 2, R. Hawman. 3, T. Armstrong.
Goldfinch Mule (Variegated).—1, R. Hawman. 2, E. Howe. 3, W. Needler.
Goldfinch Mule (Dark).—1, Moore & Wynne. 2 and 3, M. Burton.
Goldfinch.—1, J. N. Harrison. 2, Moore & Wynne. 3, W. Burniston.
Linnet (Brown, Moulted).—1, J. N. Harrison. 2 and 3, W. Nicholson.
British (Any other variety).—1, S. M'Cune. 2, E. Howe. 3, W Thompson.
Foreign (Any variety).—1, R. Harker. 2, T. Jobling. 3, D. Feerney.

Judge.—Mr. W. A. Blakston, Sunderland.

THE GLASGOW PIGEON SHOW

(North British Columbarian Society's).

THE GENERAL CLASSES.

Although throughout the country important exhibitions of Pigeons are of almost weekly occurrence, it seldom happens that reports sufficiently detailed make their appearance. No apology, therefore, is needed for noticing at some length the eleventh annual Show of the North British Colnmbarian Society, for fanciers prefer the permanence of a journal report.

The Drill Hall in Stirling Road was chosen as the scene of the Exhibition, a well-lighted room of large size and admirably adapted for the purpose, but for its excessive coldness at this season. By an inadvertence the Show was announced for a date so near to the Manchester Exhibition that a large nnmber of entries from English fanciers were lost, and the varieties other than Ponter were from this cause meagrely represented, falling short in quality perhaps even more than in quantity. It is to be hoped that such a source of loss will in future be avoided, for the Glasgow Show might easily become the representative Show of the kingdom, a position at present occupied by the Birmingham Club by reason of its greater uniform strength in all varieties.

The competition in young birds was strictly confined to members, and this is the only novelty in the schednle calling for remark. As an inducement for fanciers to join the Society such an arrangement can scarcely be canvassed, otherwise the propriety of "young classes" at all, but especially for Barbs and Carriers, is open to question. In their first season the difference of age may be so great as to place the birds on unequal terms, and it frequently happens that the awards are not justified by the after-career of competitors when brought together again in the adult classes.

Clearing the way for the Ponters—the Scotch favourites, by first discussing the general classes, we find that in *Carriers* the honours fell chiefly to Mr. Holt, a member, and to Mr. Ord, of London; Mr. Ord standing first both in Black and Dun cocks, and in Carriers of any other colour taking all the prizes unopposed. His Black and Dun cocks were, perhaps, open to the exception of being slightly down-faced, while the Dun was somewhat deficient in eye, a defect intensified by the low temperature of the hall. Mr. Holt figured as first in birds of 1869, with a very promising pair of Blacks, and in addition to some minor awards in the old classes, took the first prize in Dun hens, and the first also in Black hens, with a bird displaying considerable style—a property not nearly so much cultivated by Carrier fanciers as it deserves, in their efforts to develope head points.

It will hardly be a digression to express our surprise that any breeders of this great variety, claiming also to be fanciers, should lately have had the temerity publicly to disparage the grand properties of style in favour of head and wattle. What good reason can be given for ignoring style? The true art of the breeder is discovered in his ability to combine highly-developed head, face, and wattle with grandeur of form, size, and carriage. A musician being once asked what were the requirements to success as a vocalist replied, "One hundred things are necessary, ninety-nine times a good voice, and one good method." Just so in Carriers. We require the ninety-nine times a good head, and one grand style, but be it understood that

the one grand style is simply and uncompromisingly indispensable. Without it this bird must cease to enjoy its pre-eminence as the "King of Pigeons," a title which it had deservedly earned long before the head points were so highly developed as at present. The pernicious effect of the novel doctrine in question is becoming more and more apparent, even at our greatest shows, and it is scarcely an exaggeration to assert that some of the birds in the Dragoon classes have more pretensions to a genuine Carrier style than many of our prize-taking Carriers themselves. Our fanciers may well, then, devote their utmost attention to the maintenance of the undulating serpent neck, the prominent chest, stout shoulder, long pinion, slender girth, tight feather, brilliant plumage, the upstanding defiant attitude, and all those other items of style characterising this noble variety.

As usual, the fame of Mr. Montgomery was effectively heralded by his *Trumpeters*—all the awards in Blacks and all the prizes in Mottles falling to his share. The success of this gentleman is mainly due to an extraordinary pair of Trumpeters which some seasons ago found their way into the English market from Russia, where this quaint variety is held in great estimation. The parent bird even now maintains his superiority over all comers, and, with his heavily crowned head obscuring beak and eye, his shaggy booting and squat carriage, may not inaptly be described as the "Skye Terrier" of the Pigeon kind. Mr. Montgomery, who has made the most of his opportunity, must continue to lead in Blacks and Mottles until other fanciers meet with his good fortune, or until his strain be dispersed. In Whites, however, Messrs. W. Oates and P. H. Jones were unopposed, standing respectively first and second.

Much discussion was excited by the awards in the *Fantail* class. Fanciers of this popular variety do not appear agreed as to the strain for cultivation. Thus, while the majority affect birds comparatively coarse, of large dimensions, and of somewhat upright bearing, a select few, headed by Mr. Hnie, have been endeavouring to establish a strain of Indian extraction, more delicately framed, and of surpassingly beautiful carriage. Two such pairs, exhibited by Mr. Hnie, would unquestionably have taken the highest honours, but for the fact that they had been slightly clipped, merely, however, for the purpose of personal identification, and because at last year's show the ownership of some birds in this class was disputed. Displayed in the show pen they called forth the admiration of all who saw them, and, although neither pen nor pencil can do justice to peculiarities only to be estimated whilst the birds are in motion, we may state that they differ favourably from the ordinary variety in diminutiveness, gracefulness of form, and piquancy of carriage. In this latter particular they are simply unique. Stepping daintily on the tips of their slender toes, they seem subject to an incessant and uncontrolled tremulous motion of the neck and head. Meantime, their breasts, compact and prominent, are much elevated, while their meek-looking heads, well thrown back and touching the very base of the tail feathers, are mostly curled over to one side or the other of delicately shaped necks. Between drooping flights is poised the spreading fan of their tails, and in whatever direction the birds are viewed they present a series of the most exquisite curves. A variety so interesting must in the long run supplant its hitherto successful rivals. In the present instance it was a matter for general regret and sympathy that the happy possessor of such specimens should have been debarred the prize by the accident named. But in these days of unscrupulous marking for sinister purposes, judges are beginning more and more to feel that they must rigidly disqualify all entries open to objection; thus it has frequently happened of late that exhibitors of unimpeachable honour have innocently fallen victims, and a more conscientious exhibitor than Mr. Hnie does not exist.

The remaining standard classes brought forward little or nothing of exceptional merit. Mr. J. H. Frame, however, a member and very keen fancier, showing but three pens, had the credit of carrying off first, second, and third prizes for *Barbs* of 1869, leaving but a commendation for his fellow exhibitors. Messrs. Montgomery, Wherland, Jones, and Meff shared the awards for old Barbs, the birds requiring no comment, being in several cases already well known.

In the unclassed varieties a pair of *Damascenes*, shown by Mr. Wallace, and said to be from one of the palaces of the Sultan, deservedly attracted much attention. These birds displayed much character about the head, which is of the Owl type, and is relieved by a dark beak and thin slatey-coloured eye wattle. There are no other structural properties of novelty, but the plumage is particularly soft and delicate in effect.

As a whole, the general classes must be considered as decidedly under average merit, but this deficiency finds a compensation in the superior excellence of the Ponter classes, to which we shall direct attention in detail next week.

NOTES ON FANCY PIGEONS.—No. 15.

THE LADY'S PIGEON, THE FANTAIL.

Having spoken of the three high-class Pigeons, the Ponter, the Carrier, and the Tumbler, I must next speak (as in chivalrous duty bound), of the lady's Pigeon, the Fantail; for certain it is that all ladies greatly admire this bird, whether they be fanciers or not. Among all the varieties a lady's eye at once picks out this graceful, striking-looking, and swan-like Pigeon—indeed the bird itself looks especially fit to be a lady's pet; and the hen Fantail, if well bred, looks in her extremely delicate beauty the very lady of the whole race.

It is strange how we come to associate persons, or creatures, or things with places. Thus I have a particular local association with the Fantail. Above thirty years ago, when a little lad, I was accustomed to pass through, and sometimes stay at, a village or small town in the very heart of the Fens of Cambridgeshire, called Thorney. It is known as the "Gem of the Fens," and the contrast it presents to the bare, black, treeless earth, and black wide drains of the country around, is certainly remarkable. Thorney, like every place in the Fens ending in "ey," whether Ramsey, or Whittlesey, or Godney, is an island, or rather was one when in olden times the Fens were under water, and these islands have a different surface soil and subsoil to the fen country around; on them grow the oak, and the elm, and the beech, and especially giant ashes, and wherever these trees grew they marked out to the eye some island amid the watery waste, having a firm rich earth wholly unlike the shaking Fens around. Not unfrequently, too, as at Whittlesey, there are fine strong old houses of massive stone, and heavily timbered. These were built at great expense by the lords of the manor, for no stone was near, and were inhabited by them during parts of each year while they and their friends came down to the Fens and amused themselves with wildfowl-shooting and fishing. In those slow-travelling, or rather no-travelling days, these Fens were what the Scotch moors are now to the sportsman.

But to return to Thorney. You crossed the Wash, or an extreme inland part of it, and crept along by a straight road running parallel with a sluggish, black-looking, black-bottomed leam or drain cut by the Dutch drainers, and passing on you entered a wholly different country, for you were at Thorney, amid trees well grown, highly cultivated gardens, houses of the most respectable kind, well built and with a crust of old age upon them, all saying, "This was a respectable place a hundred years ago, and a hundred years before that, just as respectable as now." To add to this look, there stood Thorney Abbey, at least what remained of it, now the parish church. The secret of the look of the place, beside what nature had done, consisted in this, that the monks of old had been there ages ago, and a great duke had held the abbey lands (very broad ones), ever since the monks lost them. In the centre of an open space stood the great duke's great steward's house, as great a man as the duke, and infinitely greater to the trembling tenant backward in his rent; greater because the great duke never came there. He lived far away at Woburn Abbey, in Bedfordshire—very far away indeed in those pre-railway days; and at the steward's house I first saw a flight of Fantail Pigeons. I connect them, therefore, with that place.

A white pole-house octagonal and ornamental stood on the lawn; but the pretty, graceful, white Fantails loved to promenade and coo all along the flat broad top of the wall that separated the steward's house from the road. Ah! I should have liked to have seen the Thorney boy who had dared to have thrown a stone at the steward's lady's Pigeons—that boy would have been of a marvellously independent nature. Well, duke, and steward, and steward's wife have long since passed into another world. But, as I said, there I fell in love with Fantail Pigeons, and thought them, and still think them, the most ornamental of all Pigeons for keeping loose about a pretty country place. Their colour, white, looks well whether the birds are promenading on a lawn, or a gravel walk, or on a wall, or whether they are basking on a building; and especially beautiful do they look if tame and feeding in a group at your feet. Indeed, they are perfect ornaments for a residence; never straying or flying far, their beauty is always present. They have not, indeed, the cleverness of Tumblers, but are thoroughly dependent pretty little dears, like their lady admirers. They will also become remarkably tame if pains be taken. The Fantail is one of the few varieties in which the hen is superior to the cock, for a well-bred Fantail hen has a super-delicate and graceful look which no cock can boast of. Her head is thinner, her neck more slender, and she is smaller in size. Yet the cock has his special merit, for when perfectly clear, as all Fantails ought to be, there is on his neck a particular, bright silver hue, which glitters in the sun as he swells his throat to coo. This is seen, also, even to greater perfection, in white cock Pouters.

In Fantails white is the original, and therefore the best colour, and its whiteness is dazzling and snowlike—so different to the white of any variety of bird in which black is the origi-

nal colour and white merely a sport or imported by a cross, as in the case of white Barbs, whose white is but a smudgy white compared to that of a Fantail. Anglo-Indians tell me that in Hindostan, where some of the natives are ardent Pigeon-fanciers, the Fantail is a great favourite and is always white, and they admire most those birds which throw their heads furthest back. When other-coloured Fantails are shown they are always inferior, and some even ugly (to my mind); for instance, the blue birds are so, seen from behind—a white Fantail always looks best: so much does the bird owe to its colour.

Fantails, although preferring, when feeling at home and at ease, to walk on the ground or bask on a wall or low roof, and never taking a fly round, yet, if strange and frightened, will fly some distance, as over a church and across a breadth of shrubbery. It is well never to let them out in high winds, as their tails are then very burdensome to them, and prevent them even walking with comfort. Fantails seem in their disposition to be very affectionate, as you may notice that a pair are constantly sitting side by side.

I now wish to state a few words on the judging of Fantails at shows. I wholly disapprove of the judges deciding entirely by the flatness of the tail; that is as bad, or even worse, than judging Almonds simply by the head and beak. Where you find a perfectly flat tail you find usually a coarse head, a short neck, and little or no motion, and large legs; indeed, instead of a delicate bird, highly tremulous, and so elegant that every one must notice it, you get a strong-looking and coarse bird. I have been watching and breeding two opposite strains of these birds the whole of this year—the larger and very flat-tailed variety so in favour with some English judges, and the delicate *petite* bird whose head is lost behind its neck, whose motion is incessant, and whose elegance is supreme; and yet some judges appear to be guided entirely by a tail, flat I grant, but tipping forward towards the head, like an artificial thing, while the bird has no motion and little elegance of shape, and all this while the proper name of this Pigeon is—the Broad-tailed Shaker. Carriage, and motion, and smallness must be more looked to, and with them let breeders try to get as flat a tail as may be, but with the former and more valuable points well developed; the result will be the exhibition of birds which even a novice will pause over and regard as something quite unlike a common Pigeon. The coloured birds, doubtless, get their colouring from a cross with a Runt, and are often neatest in shape.—Wiltshire Rector.

ORIGIN OF THE HIMALAYAN RABBIT.

It appears to me that the theory favoured by "Duckwing"—namely, that the Rabbit commonly called Himalayan is a cross between Silver-Greys and Chinchillas—is very far-fetched and hard to believe. The distinctive characteristics of the Himalayan are so peculiar that it is difficult to imagine any amount of ingenious crossing to produce the Rabbit we now see under that name. There is generally some reason for the name of a thing, if we only knew it, and an unexpected incident occurred only a fortnight ago that induces me to believe that the breed of Rabbit called Himalayan is so called because it is common in, though not peculiar to, the Himalayan Mountains. An old Indian friend whom I had not seen for fifteen years, and who had resided all that time at Simla (the European settlement in the Himalayas), followed me into my rabbitry, without our having had a word of conversation about any particular breed. On seeing my Lop-ears he at once innocently remarked, "I have never seen Rabbits of that kind before—the Rabbits we see at Simla are all either grey or little white things with dark noses, ears, and feet." I exclaimed, "Himalayan?" to which he replied, "I never heard them called there anything but Rabbits, whatever you may call them, and, as butcher's meat is often hard to get, we all kept them for domestic use, the same as we did poultry." After a long and, to me, interesting conversation, which he had unconsciously started, I could come to no other conclusion than that their Rabbits, as he described them, were what we call Himalayans, making allowance, of course, for the marking not being so defined as with us, who have a special aim in view in breeding and showing.

Another gentleman who had spent many years in China asked not long since, when we were looking at all kinds of Rabbits belonging to a mutual friend, "How did you get these Chinese Rabbits?" We told him they were not Chinese, but Himalayan, but he assured us in the most positive manner that he had shot hundreds in the neighbourhood of Shanghai, as well as some few in the coffee plantations in Ceylon. We tried hard to shake his evidence as to the identity of the breed, but could not, and the conclusion I come to is that it is a distinct breed, and that in its natural state it mixes with no other.—B. Hudson, *Hull.*

CRYSTAL PALACE CANARY SHOW.

May I be allowed, through the medium of your paper, to inform Canary-fanciers in the United Kingdom of the following?—Mr. Wilkinson has most courteously given his consent to the following plan, and I hope and trust with all my heart it can be carried out. It is intended at the next show at the Palace to give a silver cup to the best bird in each variety, and it is proposed to raise £30 or more, to be subscribed by fanciers and admirers of the different varieties, and with this money to buy cups of the value of from £3 to £5 each, in proportion to the amount raised, and a cup will be given to the best bird in the various classes in each variety. For instance, if the first-prize bird in Clear Yellow Norwich is better *as a yellow* than the first-prize bird in Clear Buff is *as a buff*, then the former will take the cup in Classes 1 and 2, variety Norwich, and so on all through. This is the way it is intended to apportion the cups, eight in all:—

Norwich	1 and 2, Clear Yellow and Buff	One cup.
Norwich	3 to 8, Variegated and Crested Yellow and Buff	One cup.
Belgian	9 to 13, Clear, Variegated, and Crested	One cup.
London Fancy	14 and 15, Jonque and Mealy	One cup.
Lizard	16 and 17, Gold and Silver-spangled	One cup.
Cinnamon	18 and 19, Jonque and Buff	One cup.
Mules—Canary and Goldfinch	21 to 24, Clear and Variegated Yellow and Buff	One cup.
Mules—Linnet and Canary, and any other variety	26 and 27, Linnet Mules and other varieties	One cup.

Norwich have two cups, but as the classes in that variety are so numerous, and generally so well filled, it is only fair that it should be so. The number of cups will of course depend entirely on the manner the admirers of the different varieties respond to the call; if sufficient cannot be raised for any particular variety, to give at least a £3 cup, no cup will be given at all in that variety, and all the money collected will be returned; if more than enough be raised, then, on the other hand, more cups will be given to that variety which has received the extra amount, and so on. For instance, if the Norwich variety fanciers subscribe enough for four cups, then four cups will be given; if the friends of any other variety, say Lizards, do not subscribe at least £3, then no cup will be given to Lizards at all.

Mr. Blakston, of Sunderland, has kindly consented to receive subscriptions for the cups for Belgians and Mules, and I will make arrangements with some well-known fanciers to collect for Norwich and other varieties. I shall send a circular to every likely fancier, and I shall be happy to receive subscriptions from any one, and for any of the classes.

I have great pleasure in informing the Canary world that a gentleman, whose name I may not yet divulge, a great winner in poultry and Pigeons, told me on Monday last at the Manchester Poultry Show that he had nearly made up his mind to join our ranks. I only hope he will. I think, too, ere long we shall see "Wiltshire Rector's" name among the winners. Gentlemen like these will do more good than a thousand "painters and stainers."—Howarth Ashton, *Polefield Hall, Prestwich.*

DR. PREUSS ON FOUL BROOD AND INFECTION.

(*Continued from page* 496.)

We shall in the first place more closely examine Cryptococcus, as it is the parent and constant concomitant of a familiar process—viz., fermentation.

The science of fermentation is no easy one, and it cannot lie within the scope of this article to treat polemically on the various theories which have been advanced. Hallier's work on Fermentation, Putrefaction, and Decay, which I have already mentioned, affords ample information on the subject.

The original idea of fermentation was, that it is the decomposition of a fluid attended by gaseous development, but it has long been proved by scientific investigation that the development of gas is by no means an essential condition. On the other hand, it is essential that the body to be decomposed by

fermentation should be an organic one, and that a ferment or leaven be present, with the introduction and removal of which the process begins and ends. This leaven increases itself during fermentation, but only a portion of it, 1·2 to 1·5 per cent., enters into the new formation—the lees. The opinion has been maintained that it is only by contact that leaven can excite fermentation. According to Hallier's experimente, however, this opinion is fundamentally wrong. If fermentation were a chemical process to which the dreg-formation gives the first impulse, but which, if once set up, becomes self-sustaining, it would not be possible for it to come suddenly to a standstill, as frequently happens in many manufacturing processes, such as brewing, &c. Among the conditions of fermentation (as well as of the increase of the before-named mycological forms) are a certain degree of moisture, a suitable temperature, and the presence of some nitrogenous substance. Although a temperature of from 10° to 40° R. (55° to 123° Fahrenheit) is the most favourable to fermentation, the possibility of the process is limited only by the boiling and freezing points. It may also occur in the absence of nitrogen, as is proved by the fact that by the addition of a few cells to a solution of sugar, which is free from nitrogen, fermentation may be set up, although only to a limited extent.

If we examine common yeast under the microscope, we find that it consists entirely of innumerable ellipsoidal, but nearly globular, corpuscles, in which we immediately recognise the form of Cryptococcus. I find, after repeated measurements, that the usual yeast corpuscles, Cryptococcus cerevisiæ, have a length of 0·008 millimètre (1·275 line), and are consequently larger than the Cryptococcus found in foul brood, which has a diameter of 0·002 millimètre (1·1095 line). These globules multiply, as we may plainly perceive under the microscope, by forming a bud on a spot situated mostly near the longer axis, this rapidly increases, separates itself from the parent stock, and commences the same process anew.

We readily perceive from the foregoing sketch of the natural history of these forms of fungus, that we can produce yeast by sowing mildew. As soon as mildew germinates in any saccharine fluid, its spores disseminate the Micrococcus, which, if there be a trace of nitrogen in the fluid, rapidly swell and develope into Cryptococcus, the common yeast fungus. This can, of course, increase by division *ad infinitum*, but its origin is to be traced to the ordinary brush-mildew. It is necessary carefully to remember this derivation of every yeast fungus from one particular mildew, in order perfectly to understand what follows.

Now, although the common yeast fungus varies but little, if anything, in size whilst confined to the usual liquids capable of fermentation, it assumes different sizes when present in other substances. If we sow brush-mildew in fatty oil, it forms a ferment, which differs from Cryptococcus cerevisiæ in the minuteness and great delicacy of its sporules. Relying upon this fact, I explained in my first paper on foul brood that the common fermentive fungus might possibly assume the smaller form of Cryptococcus alvearis when present in the interior of the larvæ.

Now, as the brush-mildew is the first parent of the fermentive fungus, we can raise a ferment from any other kind of mildew by sowing its spores in liquor capable of fermentation, and by this means obtain different forms of Cryptococcus —*ex. gr.*, Rhizopus nigricans, Ehrenberg, if sown in bilberry-juice produces very minute cells.

The contents of fungus spores which consist of Micrococcus granules, if in contact with or immersed in substances in which nitrogen predominates, do not become Cryptococcus by swelling, but retain the kernel form, and, appropriating the surrounding nitrogen, increase ad infinitum by division.

This smallest form of Micrococcus,* the kernel-cell kernel-ferment, is the cause of most, if not all the epidemic diseases of man and of animals. Their extreme minuteness renders it possible for them to be received into the most delicate blood vessels, either through the air or especially by means of impure drinking-water. Their capacity for increasing indefinitely by division without passing into higher forms, together with their peculiarity of luxuriating not only in the body, but about houses, in beds, and on dung-heaps, accounts for their great power of propagating infection.

It is a long while since medical men first discovered a striking analogy between the fermentive process and the spread of many infectious diseases. Several decades ago they already surmised that it must be conditional upon and propagated by minute forms of vegetation. They were especially led to embrace this opinion when the cholera travelled from Asia all over Europe in 1831. One of the first advocates of the new theory was the Privy Councillor Franz von Gietl, physician in ordinary to the King of Bavaria. Even so long ago as 1831 he advanced this opinion, which has since been defined more distinctly in his subsequent works. He says:—"One cannot get rid of the idea that it is an infinitely minute organic body, such as, perhaps, the sporules of cryptogams, mildew-vegetation, &c., but so small that it cannot be made evident to our senses even by the aid of all possible auxiliaries. During the cholera of 1837, Böhm found in his examination of the mucous membrane of the intestines that a minute fungoid form was there accumulated in masses, and flourishing at the expense of the intestinal fibre. These observations were repeated during all subsequent epidemics. In 1866, F. Klob and Thomé determined this fungus form to be the cause of cholera, but it was reserved for the ingenious experiments of Hallier to throw full light upon the matter. He succeeded by means of a peculiar propagating apparatus in developing from the Micrococcus found in choleraic evacuations the higher fungus forms from which it is derived. This propagating apparatus consists of bell-glasses, under which the Micrococcus is disseminated in a soil adapted to it. As the most diverse spores continually congregate in the atmosphere, care must be taken that these do not intrude. Hence the bell-glass is first purified by being boiled out and then cleaned with alcohol, and after being placed over the Micrococcus it is insulated by means of water, which is disinfected daily. Springing from the top of the bell-glass are two glass tubes, which are luted to it, and which run in different directions. Through one of these the air is withdrawn from the bell by means of an air-pump, whilst through the other its place is supplied by air which has been passed through alcohol, by which all fungoid elements are destroyed. The sown Micrococcus being kept at a suitable temperature, now developes itself into that form of fungus to which it owes its origin. These experiments having been made repeatedly and with the utmost care, have furnished the most remarkable results. It is found that *the parent stock of the choleraic Micrococcus is the rice-blight fungus, Urocystis oryzæ*, which is totally unknown in Europe, and is, indeed, peculiar to the rice-plant only. Cholera, therefore, originates in the rice-fields of India, whence the Micrococcus has spread itself all over the globe. It reaches the ground by means of choleraic evacuations, and there (especially in dung-heaps) it continues to increase. Through drinking-water or by other means it enters into other individuals, in whom, if they are predisposed, it continues to thrive, especially on the mucous membrane of the intestines. Science, therefore, proves that the so-called Asiatic cholera is continually being imported and transported, and thus explains many hitherto most mysterious cases.

Little as these details may appear to belong to a bee paper, I yet believe that they will facilitate the comprehension of foul brood. For this reason I quote some further examples.

In the variola of sheep is found a Micrococcus from which, by cultivation, Plospora herbarum is produced. This fungus occurs on rye-grass, Lolium perenne, and this fact coincides remarkably with an opinion which is generally entertained by the most distinguished veterinary surgeons and sheep-breeders, that damaged hay is the cause of small-pox among these animals.

From the Micrococcus of the cow-pox is produced Torula rufescens. This form of fungus abounds in the milk, especially in the colostrum, of a cow which has recently calved. As cow-pox seldom or never occurs in either bulls or oxen, and as even in cows it is usually confined to the udder, it may be conjectured that the cow inoculates herself with this disease by means of her own milk.

The mycological organism of human small-pox consists of the same fungus in a different stage of development, and consequently the effect of vaccination amounts to this—that the same vegetation cannot flourish twice in the same individual.

From the Micrococcus of measles proceeds Mucor mucedo, which occurs in the excrement of man and of animals. It is probable, therefore, that epidemic measles owes its origin to open closets and middens.

In like manner it has been possible to distinguish signs of the constant presence of Micrococcus cells in sixteen infectious diseases, from each of which a distinct fungus has been developed.

I may cite, as an example of the growth of the *third stage of*

* A decimal was omitted in the second paragraph of page 495. The diameter of Micrococcus should have been there stated at 0·0004 millimètre, instead of 0·004.—A Devonshire Bee-keeper.

mildew (Oïdium), that infectious scald-head (Achorion Schönleinii) is nothing but the Oïdium of the usual brush-mildew, so that we have at once in *fig.* 3 a representation of the filaments of this form. The difficulty of its cure arises in this way: the minute filaments of the Oïdium penetrate into the interstices in the texture of the skin, whither the exterminating action of an external remedy is unable to reach it, so that even when apparently destroyed it continually springs afresh from its hiding-place. In this manner may be explained the obstinacy of many other skin diseases, which arise from the action of parasitic vegetable forms.

Numberless examples occur throughout nature of the powerful effects of the minutest forms of fungus. Of these I quote a few:—If the starch with which body-linen is stiffened contains blight-fungus, this fungus developes itself on the human skin as Pityriasis (little scab). The Oïdium of Aspergillus Ustilago produces Herpes tonsurans, which causes the hair of the head to fall off. The muscardine kills the silkworm caterpillar, which first becomes of a reddish colour, and stiffens and often dies whilst spinning its cocoon. Oïdium Tuckeri, the grape fungus, is destructive to the vine. The potato disease, often so disastrous to entire nations, is produced by Fusisporium Solana, Oïdium violaceum, and Peronospora devastatrix, all of which are proved by recent investigations to be only different forms of the same fungus.

Milk-fever arises from Bacillariæ, a rod-like form of fungus.

It may be perceived by the foregoing, that in the present advanced state of science and of scientific instruments, we are in a position to examine directly all these minute forms, as well as to prove their natural history, and, by the theory founded on their discovery, can readily explain what often appears wonderful in the manner of infection, and the transport of diseases by intermediate bodies, as well as their propagation after a long interval of time. Hallier relates an instance in which small-pox had long since quitted a room. A mason scraped the walls, and a few days afterwards was attacked by the disease. Every medical man can cite similar cases from his own practice. As all the phenomena of the vast celestial universe became explicable after the promulgation of the Copernican system, so after the discovery of the effects of these minutest forms, many terrestrial phenomena, and especially those relating to infectious and epidemic diseases, can be explained without difficulty. When the opponents of the parasitic theory say that its adherents need seek for nothing farther, they indeed accord to it the highest meed of praise that can be given. Truth demands no forced interpretation; she is throughout simple, and easily understood.—Dr. Preuss, *Sanitätsrath.*

(To be continued.)

THE BEE YEAR 1869.

QUEEN ENCASEMENTS AND LATE-BRED DRONES.

I believe it will be generally admitted, both by English and Scottish apiarians, that the bee year of 1869 opened and closed rather favourably. In Scotland, especially, we commenced with the brightest prospects. The close of the previous year found most of our apiaries in the best condition. Stores were ample, and the character of the autumnal months conduced to keep up throughout a good population, and thus to add an important element towards future prosperity—namely, a considerable number of young bees. For my own apiary, bees wintered remarkably well; comparatively few dead, and scarcely any symptoms of dysentery appeared. The result was that the opening season found my hives in splendid condition. Still the apiarian, guided by former experience, knows quite well that the best appearances in February do not always betoken future prosperity. Ample stores are good, and population excellent, but there is one individual unit, one important personage in each colony, upon whom more depends than anything else. This is the queen, and now, therefore, comes the trying, testing season of her real condition. Hence, in large apiaries we must not be unprepared, as March and April approach, for several marked changes or declensions, and probably some deaths.

As far as the weather was concerned there was not much to complain of. The bees were occasionally deterred from prosecuting their labours, but, on the whole, there was no serious check to onward progress through the spring months. Some of the best and earliest-flowering plants, such as the gooseberry, pear, and apple, afforded excellent pasturage in my own locality, and when May arrived several of my hives exhibited great advancement. Drones appeared ten days earlier than in ordinary seasons, and swarming propensities were already beginning to manifest themselves. Unfortunately a period of cold east winds prevailed about the middle of May, which in my locality evidently exercised as blighting an influence over the ardour of my bees as they did over the various products of garden and field. Hence the bees of most of my advanced hives were completely frustrated in their emigrating intentions, and the most strange anomalies, freaks, and out-of-the-way proceedings took place. Well versed and much experienced as I am in all the forms and phases of this the most interesting department of apiarian science, natural swarming, I confess I never observed so many anomalies occurring as during the past summer. This arose, as I have said, from the unfavourable weather which prevailed during the latter half of May, during which the old queens were absolutely prevented from leading off the first swarms as in ordinary circumstances.

It was about this time, the 21st of May, I think, that one of your esteemed contributors paid me a visit. The day was inauspicious, and the apiary all but silent. Right in the doorway of one of the hives a suspicious-looking cluster about the size of a hen's egg attracted my notice, to which I drew my friend's attention. On a more minute examination we found it was a queen encasement, and on dispersing the bees a beautiful queen was found lifeless in the midst. A dissection proved her to be normally fertile, the spermatheca exhibiting the usual well-known appearances in such circumstances. But for the explanation. If a stranger queen, how came she there? if the hive's own queen, why her encasement and death? My friend suggested the former, on the supposition that another hive might have thrown a swarm that returned, and the queen, missing her way, had entered this the wrong hive, and hence her captivity and death. The bad weather, however, was against this view, and, besides, the queen was an Egyptian, exactly corresponding to the one I knew the hive possessed. A few more days, however, cleared up the mystery, and showed that this was indeed the hive's own queen—a queen, too, only one year old, and apparently free from any physical disability. Soon thereafter piping commenced, and on the 28th of May, and 1st and 2nd of June respectively, three swarms issued forth all headed by young queens. In four cases the prime swarms were thus led forth by young queens, the old ones having either been sacrificed or having otherwise disappeared.

First and foremost in my apiary stood at this time another Egyptian colony, domiciled in a large straw skep, which had good stores and an immense population. This hive appeared ready to swarm about the 18th May, but no opportunity was afforded it by reason of the unsuitableness of the weather. On the 29th of May I was astonished to find a young full-grown queen extended dead. Conjecturing that this hive had been in the same position as the Egyptian hive already alluded to, I wished to try an experiment to force a swarm. I have on a former occasion adverted to a practice which I generally found efficacious in forcing after-swarms at any favourable hour of the day I chose—namely, by feeding with a little sugar syrup or honey. I wished now to see if excitement produced by another process than feeding would have the same effect. The process I meant to adopt was simply that of rapping on the upper and anterior part of the hive. Accordingly, on the morning of the 1st of June, the first favourable opportunity which occurred, and about nine o'clock, when the sun began to shine out warmly, I gave the hive several smart strokes with the palm of my hand, and went back a few paces to watch the result. In a minute or two considerable hubbub and excitement followed. By-and-by regimental files of heavily-laden bees, those sure precursors of readiness, slowly but steadily poured out. A slight hitch occurring, I again applied the alarum beat, and off they flew. Unfortunately a passing cloud damped their ardour, and the great mass clustered up and around the skep, and beneath the landing-board, and numbers on the wing began to return. I conjectured the queen had not risen, so I immediately brushed off the hive a large hanging mass of bees, to counteract, if possible, the effects of those returning upon the still rushing swarm. The queen, however, though among the bees I brushed off, did not take wing, and I now found I was too late, as the returning bees prevailed. I tried to collect as many bees as possible, by putting a skep over the queen and those brushed off on the ground, but finding that I could not secure so large a swarm as I could wish, I returned the whole to the parent hive, and thus I was obliged to be contented so far with the result of my experiment. In this *melée* a fine young queen was sacrificed, having been stung to death either by the bees or a rival. During the middle of

the same day the bees again swarmed all right. On the 3rd of June, two days afterwards, another swarm came off, went back, and finally swarmed all right on the 4th.

In another case the old queen accompanied the swarm, but no young queen ever appeared in the old hive, while in the swarm itself a sort of necine war occurred, whereby one-third of the bees were sacrificed, and the poor queen herself narrowly escaped with her life. So much as to swarming anomalies.

In early localities I think bees both swarmed well and stored well; but, nevertheless, I am inclined to think that pasturage was neither so rich nor so long-continued or productive as in other years. Where the white clover was plentiful strong hives made considerable weight, and in several localities some beautiful supers were taken; but even in regard to this, one of the best of honey-yielding flowers, it suddenly gave way, and the bees ceased to gather much from it even after it appeared in good condition. The same remark applies also, and more particularly, to the heather. The blossom appeared abundant enough, but notwithstanding the good weather which prevailed in August, the honey collected from this source was not correspondingly good. There seemed to be a deficiency of nectar secretion in the flowers, owing to the previous dry weather, and altogether the amount stored was unsatisfactory. From the 15th to the 27th of August only did my bees obtain much honey from the heath. During this period they stored at an average from 10 lbs. to 15 lbs. each, but the greater part was deposited, not in the supers, but below. In some parts of Scotland, rich generally in heath pasturage, little or no honey was collected from the heath this season. Still, on the whole, most apiaries, I believe, were found at the close of the bee season in pretty fair circumstances; and speaking for myself, my stock both as to stores and population commenced the winter campaign in excellent condition, well prepared to brave the few bleak and stormy months which lie before them. So far, however, the weather has been very trying, and unless some mild and favourable days occur soon I anticipate dysentery will be more prevalent in our apiaries this winter than during the previous one.

I take this opportunity of adverting to two subjects referred to by your correspondents, Mr. G. Raynor, and "R. S.," of dates November 25th and December 9th, on "queen encasements," and "late-bred drones." In the former Mr. Raynor has been pleased to refer to my articles and views on the very interesting and curious phenomena of queen encasements, and details with much distinctness and accuracy the case and consequences of a Ligurian queen introduced by him into a hive deprived of its own some forty-eight hours previously. My theory, as summed up in the three conclusions quoted by Mr. Raynor, had, however, no reference to such a case as he describes—viz., that of a stranger queen introduced into an alien hive. It had exclusive reference to reigning queens being encased in their own hives, and among their own bees. Mr. Raynor has, I have no doubt, inadvertently overlooked this fact. In my concluding article on this subject, February 7th, 1865, page 104, he will find a description of the kind of encasements to which he refers, together with my views, fully stated, of the various effects which follow from the introduction of stranger queens into queenless hives. I believe there is no uniform rule which obtains in such cases, for that which suits to-day may not answer to-morrow. I congratulate Mr. Raynor on his success in introducing his stranger queen without the aid of a queen cage. With it, I can only say, there would be less risk, and the lengthened encasement to which his queen was subjected would in all likelihood have been prevented.

In regard to the unusually late appearance of drones in one of the hives of your esteemed correspondent, "R. S.," it certainly very much resembles the case referred to as having occurred in my own apiary; but if I should now venture to prophesy as to the fate of this late drone-breeding hive, drawing my inferences from the fate of my own, I regret to say that that prophecy would be the very reverse of favourable. In the following spring my Egyptian hive alluded to produced drones very easily, those detestable small drones, too, bred in worker cells, which at any season are always the precursors of coming ruin. In this case also, they proved to be so. Exhausted fertility continued thus to manifest itself till June, the queen gradually decreasing in her productive power so far as workers were concerned, but continuing to produce both small and large drones, until the bees, instinctively foreseeing their impending fate, set to work, as long as materials were in their power, in constructing royal cells, and thus the old queen was in the beginning of June superseded, she having quitted the hive when the bees apparently ceased to care for her, and when rival thrones were cropping up around her. I have frequently had occasion to notice and admire this instinctive foresight of impending ruin manifested, and the benignant arrangements of Nature, whereby under such circumstances, when exhausted fertility of the queen arrives, drone-breeding as of necessity takes place—an arrangement this, so beneficent, that in numerous instances it becomes, I believe, the very salvation of the colony.

It will be obliging if "R. S." would note the proceedings of the hive referred to, and detail for the benefit of us all its future history.—John Lowe.

OUR LETTER BOX.

Brahma Pootras Vulture-hocked (*Virgon*).—We consider a vulture hock to be a disqualification for a Brahma Pootra cock. We can give no opinion about decisions at any show. We can only state that which is admitted, we believe universally, that given two cocks of equal merit in every other point, a vulture hock in one, while the other had it not, would certainly decide in favour of the latter. Your drawing shows a decided vulture hock—the only approach to one that the partiality of a judge can overlook. We advise you by all means to breed from the clear-hocked bird.—B.

French Fowls (*H. N.*).—The article you speak of appeared at great length some time since, with woodcuts of the birds. As it seems to be forgotten, we will take an early opportunity of returning to the subject.

Preserving Eggs for Sitting (*M. A. S.*).—We do not believe any eggs can be kept six months and then hatched. We do not say it has never been done, but the productive will be "few and far between." Our own practice and experience are so opposed to it, that we not only never set any egg a month old, but we choose the freshest we can. When eggs are plentiful we prefer those that are not more than twenty-four hours old. A kept egg, even if it hatch, produces a weak and sickly chicken.

West of England Poultry Show.—Mr. J. H. Nicholls, Lostwithiel, Cornwall, took cup and first prize for Partridge Cochins.

Quarrelsome Pigeons (*W. Appleyard*).—We fear there is no cure for a regular Tartar of a Pigeon; he seems only to live to make all the others unhappy, so his proper fate is a broken neck. The eccentric Eaton used to box such a bird's ears, half-drown him, fill his mouth with bitter aloes, give him bad water, and rub his food with bitter aloes. All this seems to us great nonsense. The right thing is that a tyrant should die. The only cure would be to get a bird who would master him, but he would in his turn be worse. Some time since we saw a beautiful white Dragoon cock in a common bird shop, and were surprised to see so good a bird in such a place. At once we bought him, but he was one of the tyrants. He would follow a bird over the whole loft, and from slate to slate of the roof of a large house, giving the birds no rest; and being armed with such a dagger of a bill as Dragoons have, he was most formidable. After trying every plan, pulling his wing, &c., we returned him to the shop. The man laughed and said, "He's a little fortune to me, he's sure to come back, and I dare not keep him with any other Pigeon; he's been bought over and over again." Happily these tyrants are not very common, but we have known a Tumbler to be as bad, but less capable of injury than a Dragoon. Fantails are usually peaceable.

Turbits (*Idem*).—The produce will be some point-heads and others shell-heads. Small beans or old tares are the best food for all Pigeons. Good Indian corn may be given as a change, and peas. Hempseed is very bad for Pigeons, and ought never to be given except to make them mate, or a little to tame them, as they will come on your feet or to your hand to get it.

German Paste—Food for Nightingales (*J. H.*).—Take two tablespoonfuls of melted lard, free from all salt, and heat it in a saucepan till nearly boiling; add four tablespoonfuls of treacle, keeping the pan near the fire, but not putting it on again, and stir the treacle well in gradually, keeping the mixture still near the fire, but not near enough to do more than keep it hot; stir in pea meal till the whole is a stiff, crumbly paste. About three pints and a half of meal go to the above quantity. A little mawseed should be finally strewn among it. Nightingales cannot be kept on German paste. The proper food for Nightingales is the yolk of hard-boiled egg chopped fine, with a few bread crumbs, and scraped or finely-chopped raw meat added, meal worms, and ants' eggs.

White Linnet.—*G. M'Dougall* would be obliged by Mr. Witherspoon stating what species or variety he means.

Bath-heating (*A Constant Reader*).—We have not sufficient experience to be able to enter into details respecting the bath, but enough to say that, provided you have plenty of 3-inch piping at the bottom you will have no difficulty in heating the water to 160°.

POULTRY MARKET.—December 29.

We had the usual appearances of a Christmas market—an immense show, hampers piled one on the other, great hurry and crowding, no small confusion, buyers complaining everything was too dear, sellers declaring their goods did not make enough to satisfy the senders. This has been the history of fifty past years, and it was again that of the present year. The supply of good poultry was small, and the prices were good; but as usual, there was much of an inferior quality that found a market with difficulty at a great reduction. We abstain from any quotation of Turkeys, as they are, if of good quality, valuable in proportion to their weight. If we were asked to speak more plainly, we should be compelled to give cock Turkeys from 12*s.* to 30*s.*, and hens from 6*s.* 6*d.* to 16*s.* The value of a cock Turkey is greatly increased by every pound he weighs over 18, and that of a hen by all over 9.
